

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

V. 21

PREFACE.

SOMEWHAT less than twenty years ago was issued the first number of the PHOTOGRAPHIC NEWS, the first weekly journal devoted to photography. The step was at the time believed by many to be a hazardous adventure. Photography was supposed to be not sufficiently mature, photographers not sufficiently interested in photographic literature, to render such an enterprise successful. It is true that photographic journalism was then in its feeble infancy, and that since then many journals devoted to the art have been born, and are dead and forgotten ; but the PHOTOGRAPHIC NEWS having at once made good its claims to the suffrages of photographers, and supplied the wants it was bound to meet, has steadily gone forward, yearly acquiring a deeper and a firmer position in the regard and confidence, as well as in the number, of its friends and readers. In writing the Preface to its Twentieth Volume we look back on its progress, and regard its present healthy and stable position, with very profound thankfulness and satisfaction.

The aims with which we began remain the same, although much extended and developed in application. At the outset we announced our aim to be the guide and instructor of the beginner, the medium of communication and interchange of ideas between more advanced students, and the recorder of all improvements and discoveries which may take place in the art or in the allied sciences. This position, and something more, we believe we have succeeded in filling. We have, we believe, had the satisfaction of initiating and stimulating, as well as chronicling, progress. We have endeavoured to aid the research of the investigator, as well as to record its results ; to enforce art-culture

amongst photographers, as well as afford materials in aid of such culture ; to uphold the scientific status ; and to consider and maintain its interest, and those of its votaries, whether regarded as an art, a science, or an industry. The task of watching the progress, in its every phase, of the art throughout the world, and publishing a sufficient record ; of gathering, weighing, selecting, estimating and rejecting, discussing, condemning, approving, and preserving the facts, suggestions, modifications, and improvements which present themselves from time to time for consideration, is not a light one ; but we are sustained in it by the hearty co-operation of many hundreds of correspondents and contributors, and by the confidence and approval we have had in the past from thousands of readers. We have nothing to add beyond saying that we shall not willingly fall short of the past. We will walk by the same rule, and mind the same things ; and in all respects make our journal worthy at once of the confidence and of the aid it has hitherto so bountifully received.

Thanking the large circle of contributors, correspondents, and readers we have met in our pages in the past, and hoping to meet them not less satisfactorily in the future, we conclude by wishing every one of them a successful and happy New Year.

January, 1877.

 Exhibition in London, permanent photographic, 193
 Exhibition, forthcoming, 252, 363

DECEMBER 26, 1877.]

INDEX.

Exhibition, injury to pictures at the late, 574
 Exhibition, medals at the next, 235
 Exhibition, the, 466, 508, 510, 515, 522, 531, 534, 541, 569
 Experiences, irregular photographic, 439
 Explosives, photography in measuring the force of, 313
 Exposure, development, light, 15, 28, 36, 40
 Exposures, shortening, 608
 Exposures, rapid, 67, 327, 431
 Eye of a dead body, image on the, 262
 Eye, photo-chemical action of the, 73
 Eye, photography in the, 286
 Eye, visual purple of the, 319

Faded prints, 450
 Fading of carbon prints, 504, 618
 Fading of silver prints, 503
 Falmouth Photographic Society, 480
 False pretences, obtaining money under, 480
 Fancy sketches and photographs of fact, 133
 Fashions in New York, photographic, 244
 Fashions in photography, 34
 Fashions in photo-photography, 103

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE PHOTOGRAPHIC NATIONAL GALLERY AGAIN.

A month or two back we had a say about portraits in oil and portraits by sun-painting, and pointed out that the general run of portraits exhibited at the Royal Academy, and in similar collections, were by no means remarkable for very high art, and that first-class photographers light and pose their sitters with as much taste as *savoir faire*. If our best photographers have sometimes failed to make the progress that might be expected from them after many years' study and training, it is due, we think, to the circumstance that they are taking up with the most difficult branch of the art.

A painter is often able to secure a likeness of an individual, but fails, nevertheless, in producing an artistic picture, while there are others, again, of whose work one says, "It is very nice and very pretty, but it is not a bit like you." We ask any impartial critic to look through a collection of portrait-pictures by Adam Salomon, Beijlander, Loescher, Petach, Fritz Luckardt, or Bergamasco, to name promiscuously the work of five good photographers in five capitals of Europe, and to compare these with the oil portraits by artists in the same cities, and we will undertake to say that not only in respect to fidelity, but pose and artistic excellence, the photographers will not fall much short, if they do at all, of the paintings. We will say more: that the leading photographers of London and other large capitals render a man or woman more truthfully than do second-class portrait painters in the same cities. We are not talking of "New Road photography" any more than of the daubers of signboards; but we are asserting that the best photographers in the kingdom (whose number, we admit, could very well be reckoned on the fingers) do quite as good portrait-work as the majority of those painters who show portrait work in the Academy.

It may be said that portraiture is just the weak point of our painters, and no doubt this is so. Portrait-painting, as we have said, is a very difficult art, but for that very reason we hold it to be exceedingly creditable on the part of our best photographers that they have succeeded so well in overcoming the many difficulties met with. And now that photographers have succeeded in the art of producing good and, in some cases, very excellent portrait pictures, we wish to call attention once more to a project which has already been debated in these columns—it is that of a Photographic National Gallery. We have photographers now who are artists, and we have a method, too, of producing permanent pictures. Mr. McLachlan, of Manchester, and Mr. Baden-Pritchard, of Woolwich, have been especially prominent in urging such a scheme upon the attention of the public, the latter, we believe, putting forth a practical plan for the formation of such a collection, at a lecture delivered by him seven or eight years ago at the Royal United Service Institution.

The carbon process and collotype methods have so much improved of late that the production of portraits of this kind—as permanent in their nature as oil paintings—would exhibit no difficulty at all. The chief objection, so far as we have heard, is not the fear of producing prints that were not permanent, so much as to get good portraits that are pictures at the same time. Indeed, we have heard men hostile to photography, and all things photographic, fervently remark that if such a gallery ever comes to be established, a fleeting and not a permanent printing method should be chosen, for the very reason that all the "atrocity" would perish sooner or later. Such people's idea of

photographic portraits has been ignored by placing out the enormous collection of portraits that are to be seen in many homes in which photography of every age and every quality is represented. A family album that contains portraits of friends, deceased, perhaps, twenty years ago; or pictures that have been taken by the village photographer when *cartes-de-visite* first came into being, are scarcely likely to present prints of a first-rate order, and their inferior aspect is still further increased by being in juxtaposition with other portraits taken but the other day by a Robinson or a Blanchard. Such albums as these never fairly represent the art of photography, but as, unfortunately, they exist in many households, they always have a tendency to prevent the new art from advancing beyond a certain sphere.

In the case of a collection of celebrities, men and women who have made their mark in the world, the photographers who would be entrusted with the duty of securing portraits would, as a matter of course, be experienced both in the art and technicality of the process. There would be no fear that a collection of oddities would be formed, while the adoption of a uniform and quiet style would impart an unobtrusiveness and modesty to the pictures which perhaps all photographic portraits should possess. If the pictures were well and carefully executed, of a size not so small as to require close examination to observe features, we feel sure that a Photographic National Gallery would attain to considerable importance, and be studied by everybody with interest. There is only one body in London which, to our knowledge, has gone systematically into the matter of forming a gallery of this kind. Many clubs and societies own an album with portraits of members, but these collections have many of the faults of the family volumes to which we have just alluded. But the Whitefriars' Club, in Ludgate Circus, which numbers many men well known in literature and the drama among its members, is in the possession of a large series of portraits executed by Mr. Valentine Blanchard, which, while of some considerable artistic merit, are of such dimensions (15 inches by 13 inches) as to be both handsome and well proportioned for hanging purposes. That such a scheme as we mention will one of these days come into being, is a matter on which no doubt can be felt, and the only question really is how long it will be delayed. Every year that passes loses to us some face we should delight to cherish, for negatives taken years ago get mislaid or broken, and are then beyond our power. At Munich there is a very fine gallery, representing, as well as it can, the history of painting, and in the antechamber are half-a-dozen portraits of the founders of the gallery. Were we so minded as to collect the portraits of the founders of photography, we should have some difficulty even now. Of Nicéphore Niépce, the first practical camera photographer, there is, we believe, no portrait extant, and of M. Daguerre but very few pictures are now to be found; Mr. Alderman Mayall, of Brighton, being, we think, the only English possessor of a negative of that talented inventor. Fox Talbot, we are glad to say, we have still with us, and it is our fervent hope that this father of photography in Great Britain may be spared us for a long time to come. Then there are such men as the Duke of Wellington, of whom it is very possible there may be a Daguerreotype of some sort in existence; and literary men like Macaulay, Thackeray, Hallam, &c., whose images we would not willingly let fade away. Oil paintings in plenty we have of these distinguished individuals, but who, one hundred years hence, would care to see a painted portrait of the victor of Waterloo, if they could gaze upon a veritable shadow of the great man, that has been caught up and fixed for ever? Sooner or later, we say, a Photographic National Gallery must be formed, and as our photographers are now something of artists, and we can produce pictures in permanent pigments, there can be nothing gained by postponing the establishment of such a gallery any longer.

FRENCH CORRESPONDENCE.

BOIVIN'S DRY COLLODION PROCESS—MODIFIED SILVER BATH AND DEVELOPER—DRY PLATES AS SENSITIVE AS WET—A PARIS STUDIO WITH VIOLET LIGHT—COMPARATIVE EXPERIMENTS BETWEEN ORDINARY LIGHT AND VIOLET RAYS—EXTRAORDINARY REDUCTION IN TIME OF EXPOSURE.

M. BOIVIN, of Mans, to whom we already owe several interesting communications upon the subject of dry collodion, has communicated to me the details of a process by means of which he obtains plates as sensitive as those secured by the wet process. He begins by well cleaning his plates in potash or soda solution, he washes them in ordinary water, and, finally, covers them by means of a rag with a thick mixture of chalk and water. According to his notion, success depends, in the case of dry plates, in cleaning the glass with an *alkaline* substance, while the employment of an acid under such circumstances is, on the contrary, indispensable in the preparation of wet plates. When the glass plates are to be used the white that covers them is removed with a bit of flannel, and, finally, a camel's hair brush is passed over the surface. The plates are then covered with a solution made up as follows:—

Albumen	30 cub. cents.
Water	70 "
Ammonia	1 to 2 "

The mixture is beaten to a snow, allowed to stand a while and is then filtered, after which it is applied to the plates. When the plates albumenized in this way have been well desiccated they are put away into a plate box. They are collodionized with old collodion, or, at any rate, with a mixture of old and new in the proportion of one-third of the former to two thirds of the latter. The sensitizing of the film is undertaken in a bath of—

Nitrate of silver	8 grammes
Acetate of lead	1 gramme
Water	100 cub. cents.
Acetic acid	a few drops

M. Boivin recommends that the silver bath should be exposed for a long time to full daylight, and then filtered; in this way he asserts that fogging is avoided, a defect so often observed upon dry films during the development of the same.

The plates remain in the sensitizing bath for the space of three minutes, and then they are washed first of all in water slightly acidified with acetic acid, and further with pure rain water. Then there is poured successively over the surface a solution of phosphate of soda of three per cent. strength, and another of gallic acid of one per cent., and, without washing, a preservative varnish composed of—

Water	100 cub. cents.
Pure dextrine	9 grammes
Gum arabic	1 gramme

The gum and dextrine are dissolved in warm water, to which is added a few drops of acetic acid; the solution is filtered before use.

Plates prepared in this manner are put into a drying cupboard so that they may be dried uniformly and thoroughly, and will then be found to retain their sensitive qualities for a fortnight at least. The flask containing the preservative varnish must be put away in a cool, fresh place, where the temperature is a regular one; under these circumstances it may be kept a long time without becoming turbid or decomposed.

The time of exposure in the case of plates of this kind varies, of course, with the nature of the lens employed. With a landscape lens of quarter-plate size, and a diaphragm of a centimetre opening, ten seconds to a minute will suffice for the production of a cliché.

To develop the image it is necessary, first of all, to

plunge the plate into pure water, and then into a tepid water bath; afterwards the plate is immersed in:

Water	250 cub. cents.
Gallic acid	1 gramme
Pyrogallic acid	0.3 "
Acetic acid	3 cub. cents.
Alcohol	3 "

Before immersing the film, there is added to the bath a few drops of a solution of phosphate of soda (3 per cent. strength) and a few drops of acetate of lead of the same strength, together with a few drops of acetic acid. When the plate has remained some minutes in the bath, it is taken out again, and a trace of a 3 per cent. solution of silver is added. The cliché plunged a second time into this energetic reducing agent soon becomes developed in all its details; further, silver may be added, should it be deemed desirable.

The process of intensifying is carried on as usual, and the image is finally fixed by a 20 per cent. hyposulphite solution.

M. Boivin thus sets out the theory of this process. The albumen is employed not only to give adhesion to the collodion, but more especially to endow the sensitive film with an organic substance susceptible of absorbing iodine, which is set free by the action of light. The acetate of lead in the silver bath acts in the same way as acetic acid, namely, to prevent the plates from fogging, but with this difference, that there is no retarding action.

The influence of light upon the sensitizing bath is made manifest by the reduction of organic matter, which, afterwards separated by filtration, is no longer the cause of frequent fogging, so rife among dry plates.

The phosphate of soda employed after sensitizing is used for the purpose of transforming the last traces of nitrate of silver that remain after washing into phosphate of silver, which is very sensitive to light. These traces, if permitted to remain in the form of nitrate, promptly change the impressed film. Gallic acid possesses the double property of acting as a sensitizer, and as a preserver of sensitiveness.

Not only does the preservative varnish protect the iodide of silver from contact with the air, but, like the albumen, it absorbs the iodine that is set free during the exposure of the plate in the camera; it also prevents all molecular change in the film when drying. The least washing, especially with warm water, suffices to remove the varnish, so that the reducing agent when applied at once acts upon the latent image.

The addition of phosphate of soda and acetate of lead to the reducing or developing agent augments the energy of the latter very considerably, and permits the securing of clichés of a brownish-green tone which yield very vigorous prints.

Although it is perhaps a little too early to speak of the matter, the new system of lighting with violet light, suggested by M. Scotellari, seems to gain a great many disciples. M. Scotellari has arranged, at the establishment of MM. Gilles Frères, a studio based upon his principles, from which the incredulous make their exit as converts. We ourselves assisted the other day at one of the experiments, and we were at once struck by the change that comes over the face; it is indeed a transformation that comes over every one who penetrates this violet atelier. The violet tint lends to one's physiognomy a strange charm, and one may almost say that the most ugly sinner changes at once, and assumes a beauty which he did not possess until illuminated by this harmonious light.

The experiment was as follows:—A collodionized plate was exposed to the extent of one-half upon a sitter lit up by ordinary light in one part of the studio, an exposure of sixty seconds being given; then upon the second half of the collodionized plate, after the sitter had been placed where he was illuminated by violet light, was t

a second image, but this time with an exposure of twenty seconds only. In developing, the plate was treated as if it had received but one exposure, and two images were developed, both having the same amount of vigour; in the end it was found that while in the second case, with the use of violet light, nothing had been lost by shortening the exposure, the peculiar mode of illumination had added to the detail of the picture.

From this experiment it will be seen that with an exposure of twenty seconds in violet light, it is possible to obtain the same result which, under ordinary circumstances, requires a period of sixty seconds. We shall take the liberty of returning to this subject on the occasion of other comparative experiments at which we have promised to assist.

ERNEST LACAN.

THAT DOG.

BY NORMAN MAY.

ABOUT three o'clock one afternoon, a week or two ago, an elderly lady brought an immensely fat, shaggy dog to be photographed. I took her word for its being a dog, otherwise I might have taken it for a buffalo or a bear. I explained that the day was dull, and being December it was rather late to take a dog, and wished her to bring it in the morning. Then she began, "Oh! no; I'm sure he'll be good, and the light doesn't make any difference for a dog; there's no modelling of the face, no delicate gradations of light wanted, don't you see?" I didn't quite see, though I said nothing, but thought I should like to see the photographer that could get any delicate gradations out of that dog. "You know, he's the son of a celebrated dog, and his grandfather belonged to the Prince of Wales. We call him Julius Cæsar." I didn't feel particularly interested in his ancestors, but felt sorry his grandfather arrived at years of maturity. I said I'd try a plate as she was going away to-morrow, and couldn't possibly come again, so they were ushered into the studio. When the dark room assistant heard the footsteps and creaking floor, he took one hurried glance at the huge beast, and bolted himself in the dark room, only emerging on my assuring him that it wasn't one of the animals escaped from a menagerie then in town.

The dog was quiet and docile enough, and when his mistress began again to tell me, "You know his name is Julius Cæsar, and his grandfather belonged to the Prince of Wales," &c., he laid his head down and went to sleep. He was evidently used to those words. She wanted him in a standing position, to "show his figure," as she said. I thought that if there were any figure in an old bull-frog swelled up by eating dried apples, that the dog would be just the correct thing. Just then the assistant came out with the plate, on which we could take three carte-pictures. We commenced to pose him, and, as we didn't keep a portable crane in the establishment, we had to raise him by our united efforts. We succeeded, though I've had a lame back ever since. The lady said she'd sit on one side of the studio and talk to him, as she wanted him profile in one, and she commenced to tell me of the profile of his grandfather, who belonged to the Prince of Wales, &c. He then went to sleep again. We lifted him up, and got him so as to show his profile. Just as I was about to expose, the lady requested me to wait a minute, as the expression wasn't quite right; and she began to tell me of the expression of his grandfather, who belonged to the Prince of Wales, &c. I smiled a sickly smile, and the dog slipped under the table. We hauled him up again, and this time I managed to get the cap off, and everything went on smoothly for about two seconds, when the lady began to speak again, and the dog, fancying she was saying something concerning his grandfather and the Prince of Wales, curled himself up and went to sleep.

I didn't blame the dog, but smiled a still sicker smile, and got ready for the next exposure. This time the lady thought a biscuit would be sure to attract him, as he was such a pet dog, as his grandfather was of the Prince of

Wales, &c. We got him standing again, looking as sober and elegant as a cow on ice. He seemed quite steady, and I exposed. I hadn't exposed more than three seconds before the lady said, "Biscuit! won't Julius Cæsar have a biscuit?" Julius thought he would, and walked over to get it. Of course, that one was spoiled; and then for the last space on the plate. Next time he was posed nicely, and the expression pronounced quite benevolent, so under favourable circumstances I began. Just then Julius Cæsar wagged his tail, upsetting a table behind him, and smashing a vase and things. The lady said she was so glad it didn't fall on him, as he might have been hurt.

I sent that plate into the dark room, and while the assistant got another ready, I went and made out the bill for damages. I mildly insisted on trying to get him still myself next time, and she must try and put up with a full-face view of him.

She seemed in deep distress at that, as she said the Prince of Wales had such a nice photograph of his grandfather taken profile.

I began to feel still more sorrowful about his grandfather, and dropped a silent tear of perspiration, but went on with my focussing. Next time I managed him nicely for about ten seconds, when the lady began again to tell me of Julius Cæsar's grandfather, &c. That seemed to be a sort of evening prayer for the dog, and he lay down and went to sleep. My patience was getting exhausted, and somehow I got a little tired of hearing of his grandfather, so I asked her if she'd mind going into the other room. I promised her I wouldn't take him till I was sure he had a pleasant expression, so she went, at which I was glad, as I could hear the assistant indulging in some ornamental language in the dark room, but he is a married man, so I excused him. The last two exposures I managed to get on pretty well with, and it was too late to take another, at any rate, so I gave Julius Cæsar to understand it was all over, and at parting kicked him gently for his mother. I told the lady I thought I had succeeded in getting a tolerable one, and was much pleased to hear her say, "If I didn't think it was good, she thought she could come in the morning, as she wanted a good one." As I hadn't a day to spare, I said it would do very nicely, and she went, after giving me full particulars concerning Julius Cæsar's grandfather, &c. We printed some off, and it was a very fair likeness of the beast. You could see which was the right side up by the carpet, and you could make sure it wasn't a giraffe, though that was about all. It's unnecessary to add that it didn't come in again; and I think if I had to choose between photographing two babies during an earthquake, or that dog, I'd take my chances on the earthquake.

PRINTING-IN BACKGROUNDS.

BY DR. LIESEGANG.*

It not unfrequently happens that the photographer desires to print a portrait with a different background, or to give a landscape a cloud-sky, or to impart to some picture a sort of framework which may have been secured upon another negative.

In the first case, the photographer desires to substitute, probably, a more even background for the defective one of the portrait-cliché itself. The ordinary way of cutting out a shape in paper to cover the background, and attaching it to the negative when printing, yields such a hard outline round the figure that now-a-days, when there is little retouching done, it can no longer be used. The following process, on the other hand, gives a very soft outline, as beautiful, indeed, as that of the original negative:—

Upon the collodion side of the negative is laid a piece of yellow paper, and upon the latter is traced, by the aid of a pencil, an outline of the figure, holding up both against

* Photographisches Archiv.

the light in order to do so. With a sharp penknife the figure is then cut out of the yellow paper, the same being put upon a plate of glass to facilitate the operation. The outer portion, which represents the background, is then attached, by means of gum, to the reverse side of the negative. When necessary, a little modification of the mask may be managed with a brush and some cianabar, the pigment being also applied on the glass side of the negative. On the collodion side of the negative, the outline may also be further softened with a stump and graphite.

From this negative a print is now obtained, the portrait having, of course, a white background. If the background is to be shaded or vignettied, there is placed upon the printing frame a vignette mask, or a piece of wood with an oval opening, the under edges of which are bevelled, this latter being placed about an inch or an inch and a half from the glass plate.

The print upon a white ground is laid, picture-side uppermost, upon a strong piece of patent plate-glass; upon it is put an oval or angular mask of black paper, and upon this the negative of the background to be printed in, whatever it may be, landscape, interior, stippled plate, &c., the collodion surface being underneath. Upon the glass of this negative you trace an outline of the portrait, making a line inside the figure with a brush dipped in a mixture of red oil colour and olive oil; the cut-out paper figure is then pressed down upon the glass, so as to print off upon it the red outline. With a pair of scissors the paper figure is trimmed to the red mark upon it, the glass is freed from the colour with a rag, and a second time an outline is painted with the brush more accurately than before, so that the line goes inwards over the figure. The properly cut paper figure is laid upon this outline, and over the whole is placed a thin glass plate, upon which some more red colour is applied on the border of the mask, so that no direct rays can fall upon the join underneath.

When the picture, with the vignette upon a white ground, has been printed, it is necessary, in order that the lower part should be gradually shaded, to apply some of the red colour, which is so rubbed and disseminated that the light is more or less screened off, and no sharp outlines are produced. The whole is covered with a heavy glass plate, and placed upon a movable table to print. The table is shifted from time to time to prevent the light from always acting from the same direction. As it is now impossible to get a peep at the print to see how it is getting on, it is necessary to have recourse to a photometer.

When the background has been printed in this way, the negative is taken away, and upon the print, still lying on the glass plate, is put a sheet of very thin, clear glass. Upon the latter the red colour is again applied upon the outlines of all portions which are to remain light, such as hands, face, linen, &c., and an impression of these red lines having been made upon yellow paper, masks of the latter are cut out and placed over the parts to be covered.

Upon this is laid a somewhat thicker glass, upon which the outlines of the covered parts are exactly followed with red colour. High lights, that are to be kept clear, are also covered with a few lines of red colour. The print is then exposed to the light again for a very short time, and, if necessary, shaded the while by some mechanical arrangement.

Upon the white margin, which has remained covered by the mask around the picture, may now be printed a grey tone, or some sort of fancy border. An inner mask cutting in, with this view, laid upon the print, which is something smaller than the mask, and upon it is put a glass plate or a negative, with the requisite design upon it. After this final printing the print is toned and fixed.

When the negative is hard, a better effect may be secured by printing the picture first of all to only three-fourths the proper intensity, and inserting a very thin sheet of

glass carefully between negative and paper, and completing the process of printing.

From this description many may think the process very tedious and complicated. In practice, however, it is very simple, and when some little practice has been attained in the matter, printing in this way goes on very rapidly.

NOTE ON THE PHOTOGRAPHIC SPECTRA OF STARS.

BY WILLIAM HUGGINS, D.C.L., LL.D., F.R.S.*

In the year 1863 Dr. Miller and myself obtained the photograph of the spectrum of Sirius.

"On January 27th, 1863, and on March 3rd of the same year, when the spectrum of this star (Sirius) was caused to fall upon a sensitive collodion surface, an intense spectrum of the more refrangible part was obtained. From want of accurate adjustment of the focus, or from the motion of the star not being exactly compensated by the clock movement; or from atmospheric tremor, the spectrum, though tolerably defined at the edges, presented no indications of lines. Our other investigations have hitherto prevented us from continuing these experiments further; but we have not abandoned our intention of pursuing them."†

I have recently resumed these experiments by the aid of the 18-inch speculum belonging to the Royal Society's telescope in my possession. Considerable delay has arisen from the necessity, for these observations, of a more uniform motion of the driving clock. For this purpose Mr. Howard Grubb has successfully applied to the clock the control of a seconds' pendulum in electric connection with a sidereal clock. This system works quite satisfactorily.

The prisms employed are made of Iceland spar, and the lenses of quartz. After an extensive trial of different photographic processes, preference has been given to dry plates.

The apparatus is so arranged that a solar or electric spectrum can be taken on the same plate, for the purpose of comparison, with the spectrum of the star. Spectra have been obtained of Sirius, Vega, Venus, the moon, &c.

I do not purpose in this preliminary notice to describe in detail the arrangements of the special apparatus which has been constructed, nor to offer in their present incomplete state to the Royal Society the results of the experiments. Still I venture to hope that even in this early stage of the inquiry the enlarged copy of the spectrum of Vega (α Lyræ) which accompanies this note, may not be regarded as altogether unworthy of attention.

After exposure to the light of Vega the dry plate was allowed to remain in the instrument until the following morning, when a solar spectrum was taken upon it through the half of the slit which had remained closed when the instrument was directed to the star.

The photograph shows seven strong lines, all of them slightly shaded at the sides. The two lines which are least refrangible coincide with two known lines of hydrogen in the solar spectrum.

It is expected, by means of an apparatus now in the course of construction, to obtain also any finer line which may be present in the spectrum of this star, as well as to extend the photographic method to stars which are less bright.

I need not now refer to the many important questions in connection with which photographic observations of stars may be of value.

PORTRAIT PAINTING UNDER DIFFICULTIES.

Don Maan stops me in the street one day, and with a disturbed countenance tells me that his only child—a girl of three—has been lately buried. Will I or my partner be

* Read before the Royal Society.

† Phil. Trans. 1864, p. 420.

so good as to restore her to life on canvas? I agree to undertake the work if Don Magin will provide me with a guide in the shape of a photograph.

"I am sorry to inform you," says the Don, "that my poor child never sat for her photograph."

"Then," I remark, "I will be satisfied with a slight but faithful sketch, or even a coloured miniature."

"I regret that I cannot supply you with any representation of my departed daughter," replies Don Magin.

"How, then, can you expect to possess a portrait of her?" I inquire.

"Easily enough," he answers. "It is true that I have no actual likeness of the child, but equally good guides are at your disposal. I can provide you with the little dress, the little hat, the little shoes and socks which she was accustomed to wear. I have also taken the measure of her height, and the size round her pretty waist. I can furnish you with minute particulars respecting the colour of her complexion, hair, and eyes, and I will show you a lovely child who resembles my own in many ways. Besides this, my Engracia was considered to bear a strong likeness to her father. Make her appear so also in the painting; introduce the accessories I have mentioned; take a notion or two from the girl that I will send, and I am convinced that the result will be satisfactory to both of us."

In vain do I endeavour to show the impossibility of such an achievement; the merchant will not hear of refusal, and as an inducement for me to make only a trial, he offers me a large price, promising to double the amount if I succeed to his liking.

It is a source of infinite consolation to the distressed old gentleman—who by the way is very grey and wrinkled—when I finally agree to make a trial; but I warn him that his anticipations about the result will never be realized.

Sanguine and happy, my strange patron departs, and in due course I receive the various articles he had specified. The pretty child serves well enough as a model for the proportions of the figure, and attired in the garb of her late lamented playmate, she enables me to devote every attention to the detail. I am also able to crown the little pink dress with an infantile face, whose hair, eyes, and complexion I colour according to instructions; and with the introduction of a landscape background, and with a stray flower or two arranged in the foreground, the sum-total is a pretty picture which, on that account, leaves at least a "balance in my favour!"

The portrait (?) having been placed in its gilded frame, my patron is invited to inspect it.

For many long moments Don Magin contemplates the work without uttering a word. His countenance, which I watch with an anxious eye, as yet expresses neither approval nor the reverse.

Does this portrait on my easel remind the bereaved parent of his lost offspring?

It does! yes; there faithfully depicted are the very dress, the very little hat, and the still smaller shoes which she was wont to wear in life! The figure, complexion, colour of eyes and hair, are all here to a shade. In short, a resemblance to his child gradually develops itself before the old gentleman's vision, till at last clasping both my hands, and with tears in his eyes, he declares that I have succeeded far beyond his best expectations.—*"The Pearl of the Antilles," by Walter Goodman.*

MICRO-PHOTOGRAPHY FOR GENERAL USE.

BY E. MACH.*

ABOUT seventeen years ago, when a student, I communicated to M. Auber—then director of the State Paper Office at Vienna—a proposition in regard to micro-photography, which was afterwards rejected as impracticable. I had never given the matter another thought, until a little while ago

an engineer (M. J. Popper) showed me a tiny micro-photographic newspaper which had been reduced to these dimensions in order to be forwarded to Paris when that capital was besieged in 1870-71. My scheme then again occurred to me, and as it does not even now, after all this lapse of years, appear valueless, I will here endeavour to place in writing what my object is.

I propose that micro-photography—which has hitherto only been employed for pastime and for knicknacks—should be systematically developed and employed for useful purposes.

There are a large number of very costly and very rare works in this world, of which a re-issue will never be made from the printing press, and which may be deemed works of reference rather than books for reading. How cheaply might these be multiplied, and made accessible to all in the same way as the newspaper above referred to! From the circumstance that a very large number of sheets could be photographed together, and could be reproduced within a very limited area, the process of doing so would be a very inexpensive one. Most important literary works might be in this wise furnished in a most convenient and portable form. Who would not wish to possess a map of his own country or of Europe in the smallest form, furnished with all the details of an ordnance map?

Tables of various sciences, if reproduced in the same manner, would hardly be less valuable. All reference works and books, dictionaries, encyclopædies, and the like could be treated in such a way. Even when whole works have to be reproduced, micro-photography would be a cheap way of doing it.

One main difficulty in carrying out such a project would be, doubtless, the operation of finding out the places in reading, and, in short, in the utilization of such tiny documents. The finding would have to be managed by prominent marks and signs placed on the margin, so that these would form a sort of table of contents, and instead of adopting a book form, it would be more convenient, no doubt, to have the copies in one continuous roll.

As regards the consultation or reading of such documents, I cannot, as a physicist, see that there would be any difficulty in constructing an apparatus with a double magnifier for both eyes, by the aid of which the student could read the matter as comfortably as if the type were larger. A double lens of this kind, and a means for moving the roll sideways or lengthways, would constitute the whole of the apparatus required.

Micro-photography will not, of course, supersede ordinary printing, any more than the railway has rendered driving, riding, and walking superfluous. In the way I have mentioned, however, I cannot help thinking that it could be employed with very great advantage, and would be a much greater aid to literary investigation than the ordinary type, as this is compared to manuscript.

I cannot but think that, whatever may be said to the contrary, there are very great difficulties in the way of carrying out this project; nor can it be considered a far-fetched one, since it is a plan that I myself have been urged to adopt to meet my own wants. When compelled to work far from home, and can only carry about with me a limited number of works of reference that are indispensable to my work, I have found micro-photography assist me very materially in my labours.

PHOTOGRAPHIC TEST PATTERNS.—The Landore Steel Company, the *English Mechanic* says, use photography to illustrate the character of the metal manufactured by them. A plate of wrought iron is placed on a hollow anvil, and a small gun-cotton cartridge is exploded on its upper surface, the result being an indentation and fissures all over the surface. A plate of steel is treated in a similar manner, and when photographs are taken of the two plates the quality of the two metals can be estimated by purchasers in all parts of the world as easily as if they had witnessed the experiments.

PHOTOGRAPHY IN THE PAST YEAR.

THE year 1876 can scarcely be regarded as having been a favourable year for photography. Throughout the year the weather has been unfavourable, and a glance at the commercial barometer suggests that considerable depression has attended photography as a profession and an industry. Nevertheless, it has been a year of intellectual and experimental activity, and the twelve months' history of photography as an art-science has not been without interest. There is little, however, in the way of absolute novelty or of discovery to record; but modifications, improvements, and better knowledge of existing processes, all of which form part of the steady current of progress, have not been wanting.

The wet collodion process, which still remains the accepted basis of practical photography, has not undergone any change during the year: collodion, nitrate bath, and developers remaining, as they have done for years past, practically the same thing. In this country few photographers prepare their own collodion, and hence little is done, or, at least, recorded, in the way of experiment. Existing manufacturers have brought their products to a high state of excellence, and, what is of equal importance, to an admirable uniformity of excellence. The possession of samples from two or three of the standard makers, to mix in varying proportions, and so combine their special qualities for various kinds of work, gives the practical photographer a wide and varied range of excellence, which is exceedingly convenient. The nitrate bath still continues a constant source of trouble to the inexperienced, and no specific cure for its manifold infirmities has yet been found. The selection of pure nitrate of silver and pure water, and the use of a large quantity of solution, seldom filtered and never doctored, are found, as a rule, the chief necessary elements in securing a good bath. But, in spite of all ordinary care, at times troubles come: fog, thin images, over density, matt silver stains, streaks, and pinholes. The remedies are, however, for the most part well known, simple, and efficient. No new remedies have been proposed during the year; but the use of nitrate of baryta, at the rate of three grains to the ounce of solution, for the removal of pinholes, has been further tried, and, in many cases, approved as successful during the year. The precise mode of its operation remains uncertain. Developing methods remain the same. The ordinary iron developer, in use for many years past, is still in use. Mr. Lea has suggested a new preparation of collocine for addition to the iron solution, as a means of securing vigour without prolonged exposure, which has received approval from many who have tried it. Messrs. Eder and Toth have experimented largely with the use of lead salts in conjunction with the iron developer, as an aid to intensification. Our last volume

contains details of their operations in a series of articles which will well repay perusal.

Dry processes have continued to occupy much attention. Emulsion processes have progressed in general estimation, and modifications in their preparation are still the subject of discussion amongst experimentalists; but, as in the case of collodion for the wet process, there is a tendency to permit the manufacture of the sensitive emulsions drift into commercial, and therefore experienced hands, whereby many difficulties and disappointments are avoided. A degree of rapidity not inferior to that obtained in the wet process seems, in many cases, to be attainable in dry processes. With very rapid plates, of course, greater care is required, and greater risks are involved; but we have seen during the year examples of very great rapidity in all the commercial dry plates which have come under our notice—the rapid bromide plates of Rouch, the rapid emulsion plates of the Liverpool Company, and the urano emulsion plates. The results of Herr Warnerke's sensitive pellicles are very fine, and are, we understand, rapidly produced. In point of sensitiveness, as well as excellence, Mr. Kennett's gelatine plates seem to leave little to be desired. Amongst the older dry-plate processes, the coffee process seems to have grown in favour, and by its aid some of the choicest landscapes we have seen have been produced during the year by Mr. Whitehouse, details of whose mode of working appear in our last volume.

Silver printing has not undergone any change. Few complaints are heard as to difficulties in the method, or lack of excellence in the results. Occasional troubles arise in the form of minute spots, which cannot always be traced to a source and banished, and still more frequently from causes which can be readily detected and removed. But the complaint of instability is not less frequent than ever; the subject has elicited much discussion during the year, especially in relation to the alleged increase of fading. No new thing was elicited during the discussion, but the old lesson of the necessity of precision and care in carrying out known operations, such as fixing and washing, were enforced and illustrated.

Carbon printing has been spreading during the year, and continues amongst many portraitists throughout the country to be superseding silver for the best class of work. The general quality of the work has also improved, and the average quality of the carbon prints which come under our notice is not inferior to that of silver. Many of the difficulties in the general application of the process in small establishments are disappearing as experience is obtained, but, as may be ascertained from the correspondence now progressing in our columns, there is still something to desire in various facilities for success in the work.

Photo-mechanical printing processes continue to extend in number, application, and excellence. The Woodbury-type process has assumed a recognized position amongst the industrial arts. Its excellence leaves nothing to desire and it is worthy of the extensive recognition and application the process has now acquired. Photo-collography processes are extending. Mr. B. J. Edwards has introduced a form of this process, under the name of phototint, which yields fine results. Mr. A. Pumphrey has introduced an excellent method of the same kind, an example of which is presented with our YEAR-BOOK OF PHOTOGRAPHY.

The modes of shortening exposure by the use of diffused light, either in supplementary exposures or other modes of applying it, have not been much discussed during the year; but they are, we believe, in many cases adopted. A method of increasing illumination has been patented by Mr. Vanderweyde, the details of which have not yet been published. An improved form of studio has also been patented by Mr. Slingsby, the purpose being to get better modelling and decreased exposure. So far as we have seen results, these aims appear to be attained.

Theoretical points have not received much attention or discussion during the year. The only discovery of the year is that of Captain Abney, to which we referred a few weeks ago. In the earliest days of photography various attempts were made, and in some cases with success, to develop an image upon a surface which had not been exposed to light, as described in the record of Moser's experiments, and those of M. Claudet and Mr. Hunt; but in the discovery of Captain Abney entirely different principles seem to be involved, and a more practical issue seems to be promised by the application of the discovery.

Turning to the applications of the art, there is expansion, but not much change, to chronicle. Portraiture, at all times the most important branch of photography as an industry, has not undergone much change. A pretty modification in the treatment of cards and cabinets was introduced by Mr. R. Brown in his "mezzotint vignettes." This consisted in introducing, by means of double printing, a grain or stipple into the vignetted backgrounds of his portraits, masking the face so as to protect it from the grain. By the effect of contrast thus gained the flesh appeared more delicate and soft, as compared with the apparently rough and granular character of the background. This style attained some vogue. For the rest, there has been little novelty in portraiture, unless, indeed, the extended practice of printing portraits in carbon constitutes a novelty. The use of photo-mechanical prints for the purposes of book-illustration has extended very largely during the year, and forms a most important feature in the extending applications of the art.

Photographic Societies have been active during the year, and there has been some increase in their numbers. An active Society has been revived in the West of England, and a Society has been commenced or re-suscitated in Glasgow. The Society of Great Britain is slow in recovering its old tone of activity and cordiality, a half-hearted uncertainty as to its future apparently prevailing amongst many. Its exhibition was, in the year just past, less successful than usual. The causes have been discussed, and will probably be avoided in future. The Exhibition projected by the Edinburgh Society some month ago has recently been opened, and proves to possess, in numbers and excellence of contributions, all the elements of a success which we cordially hope for it.

VIOLET LIGHT FOR STUDIOS.

ALL photographers know that the violet ray is the most energetic in its photogenic action, and from the earliest days of photography experiments have been made with a view to utilise this ray only in photography. Studios have been glazed with blue or violet glass, or their interiors have been coloured with a similar tint, so as to secure violet reflecting surfaces; lenses have been made of blue glass, printing frames have been fitted with blue or violet glasses, the aim being in all cases by utilizing the blue or violet light only, and excluding all other light, to shorten exposure. General experience has been to the effect, however, that loss rather than gain in actinic energy has been the result of displacing white glass by that of any special colour. The tendency of modern observation and experiment is to demonstrate that some degree of actinism is found in, or is associated with, all the solar rays. But assuming that actinism were found in the blue and violet rays only, and that the red and yellow rays were neutral, there is no reason why the use of blue or violet glass should diminish exposure. White glass transmits all the rays, permitting the passage of just the same amount of actinic energy as the tinted glass. If white glass kept back some portion of the actinic rays which the tinted glass permitted to pass, there would be some reason for believing in the virtue of the tinted glass. Or, if the yellow and red solar rays which,

with blue, go to form white light, were not simply neutral but had a retarding influence, then the use of a glass which excluded such rays from the studio would doubtless be useful. But general experience is antagonistic to either supposition. A simple test is easily applied. Expose a piece of sensitive paper under two strips of glass, one quite white or colourless, and the other violet; both pieces of glass being of the same thickness. This we have repeatedly done with glasses of various tints of blue and violet, invariably with one result; we have found that coloured glass always retarded slightly, the light acting most perfectly through the most colourless glass. If non-actinic rays exercised a destructive action, instead of being neutral, the exposed plate, when uncovered in a dark room, would be subject to injurious influence the moment it was removed from the dark slide. A little reflection will make it clear that unless violet light admits more actinic light than white glass, or unless non-actinic rays are destructive instead of being neutral, no possible advantage can be gained by the substitution of the tinted glass for white.

The oft-repeated theory has, however, again been revived. Recently M. Scotellari brought the subject before the French Society, describing a method which he patented of applying a violet varnish to the glass in the studio to avoid the cost of violet glass. He affirms he reduces the exposure by nearly one-half, getting, at the same time, softer, more harmonious, and better modulated negatives. How this is attained with the same amount of light slightly obscured by a coloured varnish is not explained, and does not appear clear. In the studios so lighted, which we have seen, there has not been much appreciable difference in the actinic effect, but a certain inconvenience has arisen in estimating the light and shade in the image, and a certain depressing effect in making everything everybody "look blue."

From some curious experiments recently recorded by M. Paul Bert, it would at first sight appear that the actinic rays of the spectrum in some cases exercise a destructive or poisonous effect on plants. Lighted through blue glass the leaves are supported vigorously on petioles, whilst under red light they droop and are feeble. But, strange to say, he alleges that under the influence of green light they wither and die—a circumstance in direct antagonism to the many experiments of Robert Hutton in the same direction. The especial experiment by which M. Bert supports his position consists in placing a sensitive plant in a lantern having red glass on one side and green glass on the other; the plant is seen to recede from the red glass and, towards the green glass, where it eventually withers and dies. The fact that the plant turns towards the green should suggest that it was more benefited by its action than the red, and the final death of the plant to insufficiency of the light upon which life depends.

Nevertheless it is possible that some as yet undiscovered injurious or destructive action exists in the non-actinic instead of the merely neutral character with which we have been credited, which may make their exclusion from studios desirable. Hitherto we have not met with illustrations of such a fact or any theory upon which the possibility might be based. We have met with able photographers, however, who spoke of experiences favouring the use of violet glass. If any of our correspondents have definite experience in the matter, we shall be glad to receive details.

THE INTERNATIONAL EXHIBITION OF 1878 IN PARIS.

OUR Paris correspondent has already called attention to the next International Exhibition which is to be held in Paris next year. Unlike most of the capitals of Europe, Paris can command at any moment a large attendance of visitors, not only because of its ordinary attractions,

by reason of its being so conveniently situated. From Great Britain, Germany, Holland, Belgium, Austria, Italy, and Spain, Paris is easily attainable, while to our friends on the other side of the Atlantic it is at any rate more com- at-able than most parts of our continent. For these reasons, if for no other, an International Exhibition is sure to attract visitors even if the circumstance were wanting that most people are only too glad to have an excuse for visiting the brilliant capital of the French Republic.

It is unfortunate that North Germany, as a State, has refused to be represented at the forthcoming Exhibition. As the gathering is nothing more than a symbol of commerce, and may be regarded before anything as a work of peace, this decision on the part of the German Government is much to be deplored, and it will not be surprising to hear such refusal ascribed to churlish and selfish motives. If we are to believe their own representative at the recent Philadelphia Exhibition, who reported bitterly against the German exhibits, they have much to learn by a comparison of their manufactures with that of other nations, and this is surely one reason the more why they ought to have supported the next universal exhibition in Paris.

Already a good deal of work has been done in connection with the Exhibition, and the grounds and park that are to surround the building have been taken in hand and planted. The arrangements for the reception of exhibits are also far advanced, and, in the second group of objects, consisting of educational articles and materials and processes for the practice of the free arts we find in Class XII.—photography—M. Ernest Lacan has already given the names of the jury of admission, of whom half have been chosen from the French Photographic Society. This jury, as soon as it has made its selection from the objects sent in, will have concluded its labours, and then a second jury, chosen by vote from among the exhibitors, will proceed to make such awards as they think proper.

The Exhibition is to open on the first of May, next year, and it will remain open until the 31st October. The regulations about admitting objects for exhibition are not as yet quite mature, but so far as we can learn at present, exhibitors will not be charged for the space their goods occupy. The arrangement of their objects, and such cases and stands as may be required for the proper exhibition of the contributions, will, however, as a matter of course, have to be paid for by exhibitors. They are requested to affix to every object sent in, the price of the same, so that its value will be apparent to the spectator.

The date for the sending in objects has not yet been fixed, but an intimation has been made that all goods forwarded direct to the Exhibition building will be exempt from duty, and will be delivered unopened. More definite information than this has not yet come to hand, but, as soon as further details reach us on the subject, we shall have great pleasure in laying them before our readers.

EDINBURGH PHOTOGRAPHIC SOCIETY'S EXHIBITION.

In taking a first survey of the Exhibition we are struck with the fact that even a cursory examination of the pictures displayed affords ample evidence of the firm hold which carbon printing has already taken both at home and abroad. Foremost, in point of size at least, are a number of the pictures with which visitors to former exhibitions are familiar as the work of the Autotype Company. They here contribute largely; but as most of the work has already been noticed while in the London Exhibition, we need not enter into detailed criticism. Tasschler Brothers, of St. Fiden, show twelve charming *genre* pictures (13 and 14). They are single-figure subjects with backgrounds applied to the negative by a separate operation. The pigment is a warm purple-brown, and the

surface quite free from gloss, yet the prints are brilliant and full of delicate detail. Strumper and Co., of Ham- burgh, in No. 12, have a dozen photo-mechanical prints of much interest. They are views in Ham- burgh and Vienna, and, but for the almost offensively high polish, would be readily accepted as excellent silver prints. In No. 182, Charles Schulz, of Dorpat, shows three views in Russia, of large size and well printed. T. Geldmacher, Frankfort-on-Maine, No. 874, has a frame of beautiful specimens of printing on textile fabrics and on metals; those on satin, of various tints, being specially brilliant. Goupil and Co. exhibit a dozen choice specimens of photo-engraving, re- productions from paintings, of which (676) "The Last Cartridge" may be taken as a fair sample. The Berlin Photographic Company also show fine reproductions, but they are in silver, and on that account hardly find so much favour. Lambertype and chromotype are well re- presented; C. Ferranti, of Liverpool, and J. G. Hameter, Dordrecht, each shows a frame of very fine prints by the latter process.

Enlarging seems rapidly gaining ground in land- scape as well as portrait work, and a large proportion of the exhibits consist of enlargements. Mr. Vernon Heath has a fine series of Highland scenery, and as he also exhibits prints from the 12 by 10 negatives from which they were made, we have an opportunity of judging how much loss, if any, has been sustained in the enlarging pro- cess. "Glen Slighachan" (327) and "Scour na Gillean" (328) are magnificent specimens, and show unmistakably that in some cases, at least, when the negative has been taken with a special view to enlarging, the enlargement is really finer than the small print. Mr. Wilson, of Aber- deen, is an extensive exhibitor of enlargements; and as he has recently fitted up all needful appliances for that kind of work, we have an opportunity of seeing how far success has attended his efforts. His groups of "The Queen and Princess Beatrice" (783), and of "The Queen, Princess Beatrice, and Prince Arthur" (97), are very fine. "Dr. Pirie, of Aberdeen" (512), is rather darkly printed; but No. 410, "Portrait of a Lady," is very good. Of his four frames, Nos. 296, 307, 316, and 331, of small direct landscapes in his well-known style, it would be superfluous to speak; they are quite up to his high standard; the cloud effects in No. 307 are most charming. Mr. A. Williamson shows twenty-four views of Highland scenery of more than average good quality. A few of them, such as "Glars Corrie Burn" and a "View on the Elchaig," are very beautiful. A. Kareline, of Russia, exhibits very largely, and nearly everything he sends is good. A series of groups and figure studies are well worth careful study, both as regards lighting and arrangement. Some of his effects, such as that in No. 775, where a lady and gentle- man are seated in a room lighted by a single window, are puzzling at first; but a closer inspection shows it to have been printed from more than one negative. His No. 506 is one of the most charming pictures in the Exhibition, and shows him to be a complete master of light and shadow; a lady, with a black velvet dress and white polka, is seated before a mirror, in which she is beautifully and perfectly reflected. The white portion of the dress is full of delicate detail, and yet the folds of the black robe are properly lighted, and perfect in gradation. As a whole the picture is admirable; and not the least wonderful thing about it is that it is almost, if not altogether, free from retouching.

PRACTICAL NOTES ON VARIOUS SUBJECTS.

BY CHARLES WALDACK.

Collodion in the Carbon Process.—The use of collodionized glass as a temporary support has done very much to facilitate the manipulations of carbon printing. Many accidents which occur on single transfer, and on double transfer, both by means of flexible support and waxed and resinized glass, very seldom or never make their

appearance when collodion is used as a substratum. A an instance—an over-done print on paper, whether single or double transfer, can be weakened but to a slight degree. If the weakening process is pushed far by the long-continued use of water at a moderate temperature, the gelatine films become disintegrated, or like rotted. If this be attempted by using hot water, blisters almost invariably occur. With collodion as a substratum, a much over-done print can be weakened to the proper point, whether by means of hot water or long soaking. How far the following example will show: a weak, over-done print, after having been considerably reduced, was, at the end of the day's work, left in the pan until the next morning, when the weakening process was resumed, and the print was, finally, by the long-continued action of hot water, brought to the required point. The degree of sensitiveness of prepared tissue being somewhat uncertain, it is always safe, when the right exposure cannot be exactly hit, to lean rather towards over-exposure than under-exposure, and therefore a modification of the process, which allows of great latitude, is particularly valuable. The collodion substratum has also the advantage of retaining, with great tenacity, the more delicate half-tones in the lights, which, when paper is used, are often washed away in a forced development. The physical properties of the collodion have considerably to do with the success of the operation. A very tough collodion should be used then. If too thick, the film is apt to loosen during the development; thin collodion, however, when not of a tough nature, will cause the print to adhere too much, and to detach with difficulty in the final transfer. Such collodion can be toughened by the addition of a few drops of castor oil.

Variable Sensitiveness of Bichromate Tissue.—Vigour in Carbon Prints.—It is a well-known fact that sensitized tissue increases in sensitiveness by keeping, it even varying from morning to evening. This is probably caused by a certain degree of insolubility induced by various influences, the consequence of which is that the action of light necessary is lessened. Prepared tissue, well deprived of the excess of bichromate, and rapidly dried in an air current, is in its least sensitive condition, but it is in the best possible condition to adhere well to the support, and to develop easily. It will also give prints of more vigour than that which has been kept some time. In carbon printing, the same as in silver printing, sensitiveness and vigour do not go together. Twenty-grain salted paper will yield dull prints from negatives which will yield vigorous prints with five-grain paper, but the first is much more sensitive than the last. Tissue, sensitized in a six per cent. bichromate solution, will give duller prints than that sensitized in a two per cent. solution, but will be three or four times more sensitive. This variation in the vigour obtained gives us the means of making use of both thin and intense negatives, varying only the strength of the bichromate solution. The use of several different solutions is, however, unpractical and troublesome. The same effects may be obtained in a more simple way, by using one solution and varying the length of time of the immersion. An immersion of sixty seconds will give much less sensitive tissue and more vigorous prints than one of three or four minutes. By properly timing the immersion, as vigorous prints from thin negatives can be made on carbon as on albumen paper. Most of the carbon prints made from thin negatives suitable to the old process are admired for their softness, but lack decidedly in vigour. The cause of this, I think, owing to too long an immersion. It is generally recommended to leave the tissue in the bichromate until it begins to show a tendency to curl up; this takes about three or four minutes. If this practice is to be followed, we have to go back to the kind of negatives we made fifteen or twenty years ago. If the printer troubled with want of vigour will try an immersion of sixty or ninety seconds, he will find that his prints improve considerably. In ex-

treme cases, the immersion may be shortened to twenty-five or thirty seconds, the superfluous solution being immediately removed by means of the squeegee. One caution when resorting to short immersions. It is necessary to make use of tissue which, held up to the light, is seen to be free from waves and veins, as these would in every case be reproduced in the print. The special Autotype portrait tissue is free from these defects.

RETICULATION IN CARBON PRINTS.

BY WILLIAM BATHO.

A short time since I had the opportunity to offer to the notice of your readers what I thought and still think the remedy for the sticking of carbon prints to the rigid temporary support (presuming the waxing to have been properly performed). Now it is intended to treat of a defect the name of which heads this article.

In all trades and professions there are two classes that may be divided "thusly": they who simply care to know that a certain mode of procedure yields success, and they who know this, and in addition, the reason why it does so. The former class may save themselves some time by skipping a portion of this paper; the latter may possibly benefit themselves by following me in the details of experiments that led to the means by which this difficulty has been overcome. Knowing my fallibility, it is better to give the premises leading to my conclusion. It may be added that the experiments were not performed with the specific object of "reticulation" in view, yet all other information obtained that has not in my idea some bearing on the point at issue is suppressed.

A number of tissues were taken, the temperature at which they were respectively soluble ascertained when unsensitized, and again when sensitized, and kept for twenty-four hours to dry. Here they are tabulated:—

Name of Tissue.	Temperature of Solubility Unsensitized.	Temperature of Solubility Sensitized.
Lambertype portrait ...	83.5°	92°
" contretype ...	90	95.5
Ex purple special ...	81.5	91
Auto-brown special ...	88.5	93.5
Red chalk ...	85	94
Sepia ...	85	92
Purple ...	86	96
W. B. ...	86	94
Transparency special ...	90.5	94.5

Here was a circumstance quite unaccountable: that tissue most carefully preserved from the action of light should be insoluble at the same temperature as it was soluble when unsensitized. Still, as in each case given the result was a mean of six experiments, it could not be well questioned. Yet it did not satisfy me, and other trials were made with this result, the description of which is given in the words as they were written at the time the experiments were made. "This, however, is not found to hold good, for if the water be kept steadily at the temperature given for unsensitized tissue, an insoluble film after a time leaves the face, and the tissue underneath them dissolves as freely as unsensitized. This appears to indicate some surface action—endeavour to find how brought about."

Another circumstance that gave great help on the way, viz., that those tissues from which the thickest film fell off (the thickness could only be estimated by density) yielded the results most free from reticulation, but with this disadvantage, which might have been expected, the least purity in the whites. With these facts before us let a reticulated print be examined under ordinary magnifying power it will be seen to have well defined cracks forming a network, yet this is never seen on flexible support. Possibly this defect on the rigid support, is owing to the tissue being in an expanded state when placed thereon, the drying bringing about a contraction which results in

the fracture of the film containing the picture. In the case of flexible support its elasticity may prevent this, be it as it may, a preparation of the plate, giving it a layer, having some flexibility, totally prevents the evil. This is done to some extent with the before mentioned film, as it forms no part of the picture, which is but built upon it. Two methods of doing this, at once present themselves, first a preparation of the rigid support, or a special preparation of the tissue, the former presents more trouble to the photographer than the latter would do. If a waxed and collodionized plate be coated with any of the gelatine preparations that have been recommended for developing transparencies upon, and allowed to dry, again moistened so as to cause the gelatine to swell, the exposed tissue laid on in the usual manner, and the ordinary operations gone through such prints will be quite free from reticulation. The layer of gelatine has been tried between the wax and collodion between the collodion and picture, and without collodion altogether. In two of these cases, the picture would not be "impermeable." A gelatine solution may be made for this purpose, as follows:—

Gelatine	50 grains
Water	1 ounce
Chrome alum	1 grain

It now remains to say how this might be effected in the tissue. Clearly there is a risk of degrading the whites unless the insoluble layer on the surface contains no pigment, and there is a difficulty in maintaining the mechanical condition necessary in such a compound film. With myself, however, this is as yet the experimental stage: obviously such tissue cannot be made at one operation, and must cause more expense in manufacture; further than this it is not wise to go at present.

Correspondence.

CARBON PRINTING IN COMMERCIAL PORTRAITURE.

DEAR SIR,—Your able and powerful article under the above heading, in your issue of the 15th ult., and the praise it contains of my efforts, appearing as it does to me a direct challenge, have induced me to send you a few lines, which, if they be not intended to solve difficulties, may at least be considered as the way to that end, and will probably be the precursors of full information.

To your first question, "Is it possible to make any form of carbon printing commercially available for the daily work of portraitists?" I am able to say, without hesitation, that there are several forms of carbon printing so available, and that their results can be presented in a variety of acceptable forms to suit the most fastidious—high gloss, semi-gloss, and no gloss! After this enumeration you see at once that were I to stop for a moment to explain what I have stated, I could never end this communication to be included in one of your issues; the same difficulty meets one after reading to the bottom of the first paragraph, and I must answer laconically, if I am to leave myself room to answer at all. I consider the improvement made during the last twelve months (not the last twelve years, as you put it, because the carbon processes have only been introduced to the profession for that space of time in a reliable and practical form) as absolutely marvellous, and I am justified in this assertion, when we see carbon prints which put the finest silver prints completely into the shade. The difficulties only exist for the unskilled, and the way to overcome them is by close observation and practice, bearing in mind that it is necessary to master the "art" (I very much object to your word "trade") of carbon printing, before expecting that the public will appreciate any lame result obtained on the simple plea of permanency. When a picture, more beautiful in all its aspects than the silver print, can be produced, and can carry with it the additional

merit of not being subject to fading, it will be found that the public will demand such pictures, and be content with no others. "Granulation and reticulation" are simply delusions, inasmuch as they are the result of bad manipulation.

You say very truly "that the fact of being even a skilled photographer gives no especial qualification for carbon printing." On the contrary, it is apt to get up an amount of conceit which places him who ought to learn, quite beyond the seeking of instruction. I have now come to what I consider the very best part of the article under my consideration, the cream of it, I may say, as far as carbon printing in its present state is concerned, and as the exhortation comes from you, I cannot do better than wish the words to be reprinted, much as I should have liked to have uttered them myself. "Tuition, oral or written, aptitude and experience, are necessary to success, and these aids combined are certain to bring success." These suggestive words should be well digested by all, and especially by one of your correspondents who has signed himself "An Experimentalist." And as I have just written this word, without any reference to your correspondent, who is of the right turn of mind, I would just say with Canning, speaking of his friends, "Save me from the experimentalist" in carbon printing!

You say that the great excellence to which silver printing has attained is due to the combined effort of many experimentalists and practical men: is it not singular that after a quarter of a century of all the good influences you enumerate, we should find able photographers who cannot tell you that to a certainty their prints will not all be blistered when taken out of the water; and that the prints produced now-a-days upon paper, manufactured from the freshest albumen, fade in fewer weeks than it formerly took years to alter their complexion in the least appreciable manner?

In urging upon carbon printers to communicate their experience, there is no doubt that you plead for the benefit of your readers; but you will allow me to remark that their interests cannot be served by short articles, now and then, touching upon defects or partial success achieved. What is really wanted is a careful and exhaustive treatise on carbon printing, which shall be the work of an able and successful practitioner, whose productions shall be the only admissible proof of his right to speak on the subject. That such a book can be written there can be no doubt, but it must not be forgotten that it cannot be contained within the limits of a newspaper article.

Mr. Robinson's inquiry is not exactly conveyed in the words of your article, when he says that no mention is made by another correspondent "of the use of ice or any of the various methods of producing cold"—he can wish to express no other idea than that which must relate to the temperature of the water, as it is obtained from the cold water tap when the prints have to be immersed in it previously to being applied to the support on which they must be developed. I have no doubt that he refers principally to the excessive heat which has been experienced this summer. I have been determined throughout to take no notice whatever in this, as in many other matters connected with the process, of rules laid down, and I never suffered for it—I never met with running tissue, except that which, from the consumption I made of it, helped to run up my account with the company to a pretty high figure. My carbon printing has been done in a gallery where the temperature has often reached one hundred degrees, the cold water varied from fifty-four to fifty-eight degrees, and that was precisely the time at which I had the least waste, and when some of my very finest pictures were produced, one of which was sent by a lady to Nottmann, of Montreal, who pronounced it the finest thing he had ever seen; and others—cabinets of distinguished singers which were sent to Italy. In fact, I may add that the water which was used to soak the prints for development was also used as it came from the tap, to moisten and prepare the

transfer paper, and with excellent results after five minutes' immersion. In the fourth paragraph of your letter you point to the Autotype Company, and state that to it is made the appeal for information more directly than to any one else. If I may state my opinion on this point, speaking as one of Mons. Lambert's licencees—as one consequently who has gone to the best sources of information, and has not expected to do it all on the "cheap," I deliberately say that when the company has supplied us with suitable materials, we have no right to expect anything more; and I must take this opportunity of stating that I have yet to learn that the company has ever supplied bad or unworkable tissue, as too many people would have us believe. We, as Lambert's licencees, who have paid for, and have a right to, a special tissue of a certain tint, may have had good cause of complaint at finding that, without being consulted on the subject, our tissue was manufactured of a colder tone, but even then, and much as it vexed us, we could not in justice say that the tissue was bad. In all probability the company was animated by the best of intentions, and only wished to remove the excess of fleeting pinks which had been so violently spoken against and written upon by wise men who know nothing about carbon printing, and to whom I would undertake to show that they know nothing about it even now.

You are too sensible and equitable, Mr. Editor, to expect that the Company should roll up, in every band of tissue, the necessary amount of skill, experience, and talent to produce admirable works of art. The day on which they will have discovered the admirable process by which their "magic wands"—we naturally think of those things at this time of the year—could accomplish such a miracle, I will make all possible efforts to effect a partnership in the concern.

I hope that from the above it remains established that most of the difficulties are more imaginary than real, and that the Company has nothing to do with them. My only surprise is that such splendid tissue can be manufactured after only limited experience, when it is taken into account that a quarter of a century's labours in the other direction have only resulted in a more easily deteriorated article!

C. FERRANTI.

Liverpool, December 23rd, 1876.

CARBON PRINTING.

SIR,—Our good intentions sometimes play the fool with us. I asked a question, answers to which I thought would be useful, not only to myself, but to many of your readers. But your anonymous correspondent, who signs himself "A Successful Worker," is angry with me, as an anonymous correspondent, for endeavouring to obtain information on a photographic subject through the pages of the PHOTOGRAPHIC NEWS, and recommends me to apply, with a fee, to certain teachers of the particular branch of photography—carbon printing—on which I asked a question.

The Autotype Company must be obliged to its eager tout, "A Successful Worker," for his disinterested recommendation; but it seems to me that it was scarcely complimentary to the NEWS, to which photographers are in the habit of applying for aid and assistance in their art, to suggest that information on such a purely photographic and simple matter as that about which I wrote ought not to be asked for in its pages, and that in future all such information should not be looked for in the NEWS, but should be applied for, with a fee, to the Autotype Company.

I cannot help thinking that the Autotype Company would be glad of the opportunity of repudiating the notion contained in "A Successful Worker's" letter, that they object to photographers attempting to gain any information on carbon printing except from themselves, for a fee.

Will your anonymous correspondent be shocked if I still sign myself, anonymously, A CARBON EXPERIMENTALIST?

THE USE OF CYANIDE.

DEAR SIR,—Notwithstanding all that has been written concerning the deadly effects of cyanide poisoning, and the risk that photographers run in this use of the pernicious agent to remove silver stains from the hands, the custom of washing in cyanide solution still prevails. It is a query whether the cyanide is applied in the form of solution, or whether it is rubbed on the hands in its original form. I confess that all the sad experiences which I have read in the photographic journals have failed to induce me to give up the practice of cyanide washing. I have suffered nothing, and therefore I fear nothing. This is matter-of-fact logic. I am an operator, and therefore what I have to say about removing silver stains does not apply to printers, or, at least, to those who contract silver stains by sensitizing paper. Every photographer knows that such stains are difficult to remove.

After my day's work is over, I naturally desire to go home with clean hands; and my method of fulfilling that desire is as follows:—I keep, in a stoppered bottle, a saturated solution of cyanide. I pour a small quantity of this into an ordinary beaker, just enough, in fact, to reach to the first joint of the finger. After use, this is returned to the bottle. I then well soap my hands, and dip consecutively the fingers of each hand into the cyanide solution in the beaker, and then, with a smooth piece of pumice-stone, I remove every silver stain, as easily as one could wish. I never rub my hands with a piece of cyanide, which I consider to be a bad practice, for two reasons: the pieces are likely to be broken off, and to lodge under the finger-nails; or, the hard chemical may possibly scratch the skin, and so enter the system. The soaping of the hands may, to some extent, prevent the deadly agent from entering the skin; whether it does so or not, chemically and philosophically, I know not; all that I know is, that this has been for many years my method of removing silver stains, and it is a method that I am likely to pursue for many years to come.—I am yours truly,

J. KAY.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—At the next meeting of this Society, on Tuesday next, at 5A, Pall Mall East (when the Exhibition of the Water Colour Society will also be on view), a discussion will take place on Carbon Printing, to be opened by Mr. S. Fry.

A URANO-PHOTOMETER.—The intensity, colour, and polarization of the diffuse light of the sky in different parts has recently been a subject of study by M. Wild, of the St. Petersburg Academy, who has endeavoured to measure it with a somewhat complicated instrument devised by him, and named a "urano-photometer." Referring to the Academy's *Bulletin*, for the account of this instrument, we may here give briefly the results at which M. Wild has arrived:—1. Proceeding from the sun in a vertical circle northwards, it is found that the colour of the light gradually changes from the red end of the spectrum towards the violet, and at about 80° distance from the sun it reaches about midway between the Fraunhofer lines C and D (corresponding to a wave length of 0.000528 mm.); from there on to the horizon the colour gradually goes back towards the red end of the spectrum. Thus, in St. Petersburg at the time of equinox, the sun having about 60° zenith distance, the colour tone of the diffuse light at 80° angular distance (in a vertical circle) is mostly pure blue, and passes on either side into green. 2. The saturation of the colour appears to reach its maximum at 90° distance from the sun, where also the degree of polarization is a maximum. On either side of this maximum the degree both of polarization and of saturation of colour decreases pretty regularly. 3. The intensity of the diffuse reflected light of the sky appears, on the other hand, to be at its least at about 80° distance from the sun, and from there it increases less quickly towards the horizon than towards the sun. Thus, while at 140° distance from the sun the intensity is about five times greater than

at 80°, at 20° distance it is over seven times greater. Southwards from the sun the intensity is considerably greater than northwards for the same distance. Thus, at 20° distance southwards it is nearly twice as great as the same distance northwards. These researches are being further prosecuted by the author.—*Nature*.

OXIDIZING AGENTS.—We are frequently asked by correspondents to name some of the leading agents employed by chemists to produce what is called oxidation. The operation is an important one in the arts, as upon it depends the success of bleaching, disinfection, and similar processes. We will mention some of the methods now preferred by chemists for the purpose indicated. Ozone, if it could be cheaply made, would be almost invaluable, but the cost of production stands in the way of its common use. The permanganate of soda or potash is a chemical compound that cannot be excelled in its oxidizing properties, and its use has gone on steadily increasing for years. In England, under the name of Condy's fluid, it is a common article about the household, and for hospitals and bleacheries it is coming into vogue. A little more knowledge of its value would soon lead to its production on a large scale. Bleaching powders have long been known and used as oxidizers, and, as they can be had in any quantity, are likely to continue to be employed. Chromic acid, whether in saturated or dilute solutions, has the power of converting carbonic oxide into carbonic acid readily and completely under ordinary temperatures. Ammonia gas is powerfully oxidized by it, and it readily destroys organic matter. The chlorates and nitrates can also be mentioned in this connection.—*Scientific American*.

INK STAINING.—Grimm, in the *Polytechnisches Notizblatt*, proposes the following method for removing indelible ink and other silver stains without the use of cyanide of potassium. Chloride of copper is first applied to the taint; it is next washed with hyposulphite of soda solution, and afterwards with water. It is said that this may be employed on coloured woven cotton tissues. For white cottons and linsens, dilute solutions of permanganate of potash and hydrochloric acid, followed by the hyposulphite of soda and clear water, is preferable. For cleaning the hands, iodine dissolved either with iodide of potassium, or in alcohol, is used, following by aqueous ammonia.

ENCAUSTIC COLOURS.—Encaustic colours are the various metallic oxides given in the following list. When more than one substance is used for colouring, the proportions must be varied to suit the tint required. For violet, use iron or manganese with soda; for purple, chloride of gold with tin and chloride of silver; for black, iron, manganese, uranium, and iridium; for blue, cobalt, carbonate of cobalt, smalt or silicate of cobalt. Zinc will brighten blue colours. For indigo, use the materials employed for both violet and blue; for turquoise, use copper with soda, or cobalt with man and soda phosphate; green may be obtained with copper, either with or without antimony, or by chrome with cobalt; for bronze green, use nickel. Zinc, or carbonate of zinc, will brighten this colour. For olive green, use nickel with cobalt; for yellow, use antimony with potash, titanium, chromate of lead, and chromate of barytes. Zinc will brighten this yellow. For buff, use the materials for yellow, with iron, sapie, sienna, ochre, and umber; for orange, use uranium, or the sulphide of antimony with iron; for red, use iron, chromate of iron, sulphate, copper, and ochre; for carmine, chloride of silver; for pink, iron and chrome, with potash; for brown, use iron, chromate of iron, manganese, with or without cobalt, ochre, and hammer oxide; for grey, use iron, cobalt, iridium, platinum, titanium; for white, white clay and five per cent. of oxide. The colouring oxides are used in quantities of from five to ten per cent, sometimes from fifteen to twenty per cent. No definite rule can be given for quantity. Some of these oxides act as fluxes, and great skill must be used in their employment, in order to prevent the melting of the tile. For the preparation of these colouring agents, and for other very important information relating to pottery, Beckwith's work on "Pottery" will be found a useful work of reference.—*English Mechanic*.

To Correspondents.

P. BROWN (Hants Home).—For architectural and other views in confined situations the lens you indicate by A is decidedly the best; and for ordinary landscapes D is decidedly preferable to B, or, indeed, to any in your list.

M. G.—There is no necessity for transparencies intended for ornamentation of windows to be varnished. They should always be covered with glass, or, if fixed in the window, they should be placed with the face in contact with the glass already in the window. 2. So far as our experience goes, wooden baths, lined with pure india-rubber, answer perfectly.

F. BATHMAN.—If you dissolve 6 ounces of protosulphate of iron in 10 ounces of water, you will obtain a saturated solution. From these figures you can calculate the proportion required of a saturated solution to make a developer of any strength you require.

J. R. TUNNICLIFFE.—There is undoubtedly promise in your work produced under such difficulties, and with so little practice. Take pains and persevere, and you will doubtless succeed. No. 1 is best, and would have been very fair with better facilities for controlling light and shade. No. 2 suffers from the same cause, and is moreover a little under-exposed and over-intensified. In No. 3 the sitter has moved, otherwise it would be pretty good. No. 4 is best. You will improve when you obtain better appliances. Try to get some good examples, and work up to them.

R. T. W.—For all large negatives we prefer patent plate for safety, but it is quite possible that, in certain hands, crown glass may serve, which is, of course, lighter to handle and lighter in cost. 2. If you wish to transfer a negative film to paper, for printing purposes, a piece of thin Saxe paper will answer well. It should then be waxed at the back. 3. As a rule wet plates are used for making enlarged negatives from transparencies, but in some cases an enlarged transparency is used, and printed by contact on a dry plate. Any kind of dry plate may be used, that with which you are most familiar will answer best. See Captain Atney's article in our Year-Book just published.

RALPH FOSCOLO.—No. A acquires no exclusive right, and B is at liberty to photograph the same or any other point of the same building, that is, in photographing a building or landscape, or indeed any subject which he may have the right and opportunity to photograph, a photographer acquires no exclusive copyright by priority. Any one else may photograph the same building or landscape, or indeed any subject, by its owner's permission, without infringing on the copyright of the preceding photographer. In short it is copying the existing photograph, not photographing the same subject, which constitutes piracy.

J. C. HAYDN.—The maker you name has been dead many years, and the establishment no longer exists. The cause of the defect you name is simply the fact that it is a lens of inferior manufacture. We have seen some pretty good instruments bearing the name, but the manufacture never stood high. The only cure available for the small field which is in focus is the use of a central stop. Take a piece of blackened card, make in it a circular aperture of half the diameter of the lens, and place it a little distance behind the front lens. You will find this materially extend the field of definition, but of course the exposure will be increased. The image on the plate having no definition, whilst the image on the ground glass had, is due to one of two things: either the dark slide is at fault, and does not place the sensitive plate in the same plane as the ground glass, or the chemical and visual foci of the lens do not coincide. Try the first by careful measurement, and if the plane of the sensitive plate and ground glass are found to be absolutely coincident, you may conclude that the fault is in the lens; and in that case note in which direction the focus errs, and make allowance for it in focussing, turning the focus in or out as may be required, after getting the image sharp on the ground glass.

E. B. WIGGLESWORTH.—Thanks. We shall insert the description in our next. The little instrument to which we referred was simply a small roller for running over the print and pressing it down after pasting and laying it on the mount.

J. KAY.—Thanks. We shall have pleasure in hearing further from you.

F. V. L.—When sugar is used in the iron developer less acetic acid is necessary. It acts as a restrainer both mechanically and chemically. We have used, with advantage, 60 grains of sugar-candy to a 20-grain iron solution without any acetic acid. Different kinds of sugar have varied restraining qualities, brown sugar restraining more than white sugar. Treacle is a very powerful restrainer.

G. B. P.—For many small subjects, and most if not all large pictures, paper negatives answer well. It is, of course, a matter of taste, but for many subjects we prefer them. The simplest mode is simply to take a transparency enlarged to the full extent at first. This should be intensified so as to secure a vigorous image on paper, and it may be worked on as may be required. Then take a sheet of thin Saxe paper, and float a long time, print deep, fix without toning. You will obtain a negative which will print well, and will admit of any amount of skilful retouching. Of course it should be waxed, and to some granulation do not try to iron out all the wax which the paper has absorbed.

Several Correspondents in our next.

The Photographic News, January 12, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE "TIMES" AND PHOTOGRAPHY—THE PHOTOGRAPHING OF SOUNDS ACCOMPLISHED.

The "Times" and Photography.—In a recent review of the Royal Academy album, the *Times* makes some curious and amusing blunders on the subject of photography. The art is such a general scapegoat that it seems but the acknowledged duty of every critic to point out its shortcomings, and, as it progresses, to patronise its results after a fashion. If literary reviewers would confine themselves to their proper duty of pronouncing a work good or bad, and to calling attention to its qualities from a literary or artistic point of view, all would be well, and, whatever might be their prejudices, one could find but little fault: but when, a few months back, the *Athenæum*—which, though it professes to be a scientific journal, is, as everybody knows, nothing of the sort—goes out of its way to appear clever, and suggests the boiling and steeping in hot water for some hours, in order to test it, of ordinary print and paper, simply because the same happens to be termed a photo-zincograph, one cannot but wonder where the writer could possibly have picked up the curious information he retails. The *Times*' reviewer has lately been distributing some gratis information of the same kind, which is worth about as much as knowledge of the kind usually is. Instead of confining himself to a criticism of the book before him, he must needs inform his readers on the subject of photography, and tell them what he knows about the art. This is not much. His theory of the action of photography is summed up in a few words: the pictures in the album, he says, are produced by the Woodburytype process, "in place of the ordinary process of silver photography, by which, we understand, is meant the production of the picture in the monotone of brown, which the oxide of that metal yields under the action of the sun." Our reviewer then goes on to make the matter clearer still, for fear his unscientific readers should be lacking in comprehension. "When it is understood how very distinct this (Woodburytype) is from photography or from printing, it will at once be seen how advantageous it is. The one is a chemical change, in which a colourless salt is decomposed by light, depositing its more or less black oxide in all the degrees of intensity necessary for a picture; the other is a mechanical process, in which a pigment is applied to a metal surface bearing a sort of stereoscope from the original photograph." Our reviewer is very scientific with his oxide of silver—or, rather, oxyde, as the *Times* prefers to call it—but the explanation is hardly so clear as it might be. First, he talks of a brown colour, "which the oxyde of that metal (silver) yields under the action of the sun," and then he tells us immediately afterwards that the result of the light acting upon a colourless salt is a "more or less black oxyde." Further on, again, he talks of "films of metallic oxyde" forming the photograph, so that it is difficult even for the most easily satisfied reader to understand what is meant. In any case, however, none will be more surprised, we feel sure, at this new theory of photography than photographers themselves. Woodburytype, the reviewer would have us know, is "distinct" from photography and from printing; he seems to think that negative taking is altogether dispensed with in regard to it, for he says that "the strong reds, blues, and yellows of some of our very positive colourists are conquered better than we ever see them in simple photography." The great advantage of permanency, which is one of the chief points claimed for Woodburytype, is somehow lost

sight of altogether by our reviewer, who has gone in strongly for the chemistry of the affair, while neglecting other matters of interest. This is a pity, for while his scientific opinion contains the element of novelty, it is one, we think, that will hardly receive the unanimous support of chemists in general.

The Photographing of Sounds Accomplished.—In August last we made some remarks in these columns upon the possibility of photographing sounds, and we pointed out what had already been done in this direction. M. König, of Paris, had already made some experiments, which proved, beyond a doubt, that the photographing of sounds was hardly an impossibility, but we did not suppose that the feat was then on the eve of being accomplished. M. König's researches were conducted with flames upon which various sounds were made to act, and the behaviour of the flames under such circumstances was carefully noted and sketched. Dr. Vogel, of Berlin, pointed out that by providing a revolving mirror with clockwork, so that it might revolve at a given rate, there should be no difficulty in obtaining an impression in the camera of these curves made by the flame, provided a light of sufficient intensity were employed to act upon the sensitive photographic plate. Such a method has, however, not been adopted by Dr. Stein, who has recently succeeded in photographing tones. This physicist has solved the problem by securing a record of the vibrations of a tuning-fork on string. If it is a tuning-fork that is to be employed, he fixes the instrument in a horizontal position, with its two branches in vertical planes. Through the upper branch of the fork is pierced a tiny hole, through which a bright ray of light passes on to a collodionized and sensitized plate beyond. This plate is movable, and when a clockwork arrangement is set in action, the film moves rapidly in a perfectly straight line. On the tuning-fork being struck, the branches of course vibrate, and the ray of light is naturally enough moved up and down with the vibrations. Instead of a straight line being traced upon the moving sensitive plate, as would be the case if there were no vibration or up-and-down movement of the ray, there is a wave-like mark, each wave representing one vibration. The number of waves within a certain space may be counted, and then the observer finds out the note that has been sounded. Sounds inaudible to the human ear may be photographed in this way, so delicate is Dr. Stein's apparatus, and by fixing discs upon a series of strings, each disc having a tiny orifice, he is enabled to record half a dozen sounds or notes at once, these being recorded on the sensitive plate by as many wave-like lines. Nor does this means of recording sound merely give us the number of vibrations. The waves themselves, it appears, furnish, as depicted upon the sensitive film, much food for study; they are more bright at the bend of the line than elsewhere, while the loudness of the sound is represented by the height of the waves. We have here, therefore, one more valuable application of photography to science, the first important one, we believe, that has been proposed for the investigation of acoustics. It is not, however, the only application of our art which Dr. Stein has made of photography in scientific matters. That gentleman's mode of registering the pulse and beating of the heart by the aid of photography, of which we gave an account in these columns not long ago, is one of the best methods that have been proposed for such a purpose since Dr. Ozanam pointed out the use of photography in this connection. In this instance Dr. Stein also employed a perforated disc, and we have no doubt that this last successful experiment of his is only one of the series with which he has been occupied for some years past. There is every reason to suppose that this last happy application of photography will help us to add materially to our knowledge of sound, and probably of light also—two branches of physics which still present many obstinate problems awaiting solution.

EDINBURGH PHOTOGRAPHIC EXHIBITION.

REPORT OF THE JUDGES

Appointed by the Exhibition Committee to award the Medals offered for Competition at the Photographic Exhibition in the Royal Academy National Galleries in 1876-77.

Your judges, having examined the pictures sent for competition, are unanimous in deciding on the following awards:—

1st. The gold medal for "the picture which possesses the highest degree of merit, irrespective of size or subject," to A. Karoline, Nigoy, Novgorod, Russia, for his picture (775). *Characteristics.*—Invention applied to figure subjects under skilful arrangement of light.

2nd. A silver medal for the best landscape of 8½ by 6½ or under, to Mr. William England, 7, St. James' Square, Notting Hill, for his picture, "The Wetterhorn" (768) from a dry plate. *Characteristics.*—Fine, aerial perspective, with both foreground and extreme distance in good keeping.

A bronze medal for the second best picture of the same class, to Mr. H. A. H. Daniel, 49, Broad Street, Bristol, for "On the Froom" (724). *Characteristics.*—Good choice of subject, and vigorous treatment.

3rd. A silver medal for the best landscape above 8½ by 6½, to Mr. Payne Jennings, Belgrave Place, Bathmies, Dublin, for No. 4 of his frame "Picturesque England and Ireland" (233). *Characteristics.*—Singularly clear in definition, perfect aerial perspective, and strongly expressed foreground combined with much delicacy.

A bronze medal, for the second best landscape of this class, to Mr. George Wardley, St. Ann's Square, Manchester, for his "Aberglaslyn," near Reddallert (162), from a collodio-albumen plate. *Characteristics.*—All the works of this photographer are worthy of attention, in respect to the treatment of his subject, and particularly fine in mid-distance.

4th. A silver medal, for the best portrait, from 8½ by 6½ to 15 by 12, to Mr. J. M. Young, Llandudno, for his "Hide and Seek" (457). *Characteristics.*—Although this work is titled "Hide and Seek," and a study, your judges cannot but recognise it as a portrait, and one possessing very much the qualities of the work of Sir Thomas Lawrence. The expression of eyes is beautifully sustained.

A bronze medal, for the second best portrait of this class, to Mr. James Howie, junr., Princes Street, Edinburgh, for his portrait of a gentleman (266). *Characteristics.*—This work does not embrace much treatment, but your judges regard it as a specimen of very true rendering, without the aid of modelling the negative, and thus preserving the natural texture and lines of the face.

5th. A silver medal, for the best portrait above 15 by 12, to Mr. Marshall Wane, Douglas, Isle of Man, for his portrait of Miss Carlotta la Ulerq (225). *Characteristics.*—Fine arrangement of the figure, and perfect rendering of the texture in the different fabrics.

A bronze medal, for the second best picture of this class, to Mr. J. M. Young, Llandudno, for his "Study of White Drapery" (56). *Characteristics.*—Portraiture treated pictorially, and great regard to sustaining the colour and tone of white drapery, without chalkiness.

6th. A silver medal, for the best landscape by an amateur, to Mr. Robert Crawshaw, Cyfarthfa Castle, Merthyr Tydfil, for his "Boat Pool, River Usk" (52). *Characteristics.*—Great refinement in quality, with sky in beautiful harmony.

A bronze medal, for the second best picture of this class, to Mr. John Foker, 116, St. Vincent Street, Glasgow, for his "Poland House" (75). *Characteristics.*—Very rich in quality, skilfully produced by side-lights, and, consequently, but much breadth of effect.

7th. A silver medal, for the best genre picture, to Mr. H. F. Robinson, for "His Own Fire-

side" (544). *Characteristics.*—Many of the works by this gentleman are highly meritorious through the skill displayed in combining separate negatives, in order to make one picture; but this work has the appearance of being simpler in its contrivance, and tells very directly its own story.

A bronze medal for the second best genre picture, to Mr. George Nesbitt, Bournemouth, for his "On Guard" (415). *Characteristics.*—This gentleman is very prolific in his art, and, although his backgrounds are somewhat faulty, he succeeds well in uniting his subjects.

8th. A silver medal for the best combination picture, to Mr. Adam Distin, Leven, Fife, for "The Broken Toe" (547). *Characteristics.*—This gentleman is singularly successful with a method of combining several figures on one plate by the super-imposing of various films, one after another, till the picture is complete. Your judges understand that this method was first introduced by Mr. Johnstone, of Wick, a specimen of whose work is to be seen in No. 356, wherein both sky and sea are united.

A bronze medal for the second best picture in the same class, to Mr. Samuel Fry, Kingston-on-Thames, for "The Taxidermist" (513). *Characteristics.*—Very much elaborated, chiefly created by the subject. The quality throughout is very perfect, and worthy of the closest inspection.

9th. A silver medal for the best single figure study, to Mr. R. Faulkner, Kensington Gardens, London, for his "Studies of Expression" (627). *Characteristics.*—Very original in style, and surpassingly beautiful in expression. Altogether, this artist is completely at home with children.

A bronze medal for the second best pictures in this class, to Messrs. Taeschler Brothers, St. Fiden, Switzerland, for their studies (13). *Characteristics.*—Very careful study of arrangement in all the work, and the sentiment and feeling in children exquisite. The general arrangements of the ladies' portraits are finely elaborated in combination with both natural and artificial backgrounds.

10th. A silver medal for the best reproduction from painting in oil or water-colour, to the Berlin Photographic Company, for "The Angela, by Raphael" (706).

A bronze medal for the second best picture in the same class, to Mr. John Pouncey, Dorchester, for his reproductions on wood and canvas (719, 720, and 726).

11th. A silver medal to the Autotype Company, London, for general excellence in the enlargements exhibited by them.

Your judges, in connection with this award, desire to state that although the process of enlarging is fully represented, there are comparatively few specimens that are actually the work of the exhibitor, and they have in consequence resolved to take the responsibility of slightly varying the conditions on which the medal was offered, and award it as they have done.

A bronze medal for the second best enlargement, to Mr. Benjamin Wyles, Southport, for his portrait of Miss Braddon (834). *Characteristics.*—Not unlike Sir Joshua Reynolds' in breadth and simple treatment.

12th. A silver medal for the best photo-mechanical print, to Messrs. Goupil and Co., London, for their reproduction of "Reconnoitring" (661).

A bronze medal for the second best reproduction, to Mr. B. J. Edwards, London, for his portraits (606).

13th. A silver medal for the best enamel, to Herr Goldmacher, Frankfort-on-Maine.

A bronze medal for the second best enamel, to Mr. W. T. Watson, of Hull.

15th. A silver medal for the best photograph, by an amateur who is also a member of the Edinburgh Photographic Society, to Mr. Geo. A. Panton, Edinburgh, for his "Maiden Bridge" (270). *Characteristics.*—Composition very good, clear, yet full of atmosphere, and quite equal to the work of some of the best professional landscapists. A bronze medal to Mr. R. G. Muir, Edinburgh, for the same

subject (105). *Characteristics.*—The two frames shown by Mr. Muir contain several fine bits of natural scenery. The Bridge is exceedingly beautiful in quality, owing to a full development of light.

In addition to the awards provided for in the prospectus of the Exhibition, there are several classes of exhibits not included, to which your judges would respectfully direct your attention. They would recommend that a special silver medal be given to Mr. Frederick Hollyer, of Pembroke Square, London, for his studies of Rustic Subjects, of which 473 is an example. His aim in this department has evidently been to make provision for pictorial purposes, to meet the wants of many artists in that walk, and in this respect he has been successful.

Your judges are also of opinion that a special medal should be awarded to Mr. J. Ganz, of Brussels, for his transparencies, both for decorative and educational purposes. His lantern pictures, including physiological, botanical, and mechanical specimens, are simply perfect.

Your judges think it right to say, that in all classes of exhibits, they had in many cases much difficulty in arriving at a decision (there were so many pictures of equal merit, that it was often matter of extreme difficulty to make the necessary award), and that many of the pictures that were marked "not for competition," are of the highest excellence.

Your judges have examined several frames of portraits in which very beautiful effects are produced by modelling and retouching, such (for example) as those by Mr. Gutekunst, of Philadelphia (501), and Herr Kosmata, of Budapeston (836); and although the results are undoubtedly very pretty, they consider that it would be unfair to place them in competition with pictures printed from the original and comparatively untouched negatives.

LIGHT, EXPOSURE, AND DEVELOPMENT.

BY H. A. H. DANIEL.*

THE subjects which I have chosen for my paper are, perhaps, those demanding the most strict attention of every photographer aiming at work of the highest and most artistic class. To those who are content with what the apparatus and chemicals will produce almost independently of themselves, this paper would prove most uninteresting, superfluous, and, in short, not worth wasting time over. But I am happy in feeling perfectly assured, that to such, I have not the remotest chance of addressing myself this evening. I have done my best to bring together, in a modest way, certain results and facts that have come under my notice; but it were unreasonable for me to hope that all, or even the greater part of them, would be new to you; I therefore ask your forbearance with me should I revert to matters with which many may be already familiar, although here and there they may perchance be fresh.

I have divided my paper into three subjects, the first of which is

LIGHT.

Of this we know there are two kinds, viz., natural and artificial, the former being composed of seven primary colours, which may be classed as follows—actinic and non-actinic. Artificial light may be produced in a large number of different ways, of one or two only of which I shall speak presently. One of the most evident effects of light is its power of changing the colour and nature of substances which come under its influence—glass, wood,

vegetation, chemicals; in fact, almost every substance is more or less affected by it. The first substance I mentioned—glass—is wonderfully changed by its action, although it may be a long time before we notice it. Some time since, I saw certain fixtures removed from the surface of some plate glass, and to which they had been affixed for a very considerable period, some years; it was then very manifest to what an extent the colour of the exposed parts of the glass had been changed, and by changed I mean darkened. If, after some years, those letters we often see upon the glass of shop windows be removed, very often a most perceptible difference is apparent. The knowledge of this fact is of great importance to photographers, and should act as a forcible caution, to them to expose their lenses to the action of light as little as possible—in fact, not at all beyond what is necessary during absolute work. But while on the topic of lenses, I would just remark that because a lens may look yellow and discoloured, it does not follow that it is so. Very often the cementing balsam in lens combinations will be rapidly acted on by light, being turned to a yellow tint, and making the lens appear discoloured when it really is not. We often find in the practice of photography, that in a very dark and badly lighted situation there is an object very worthy of the camera; but a photographer should never settle down under the idea that to get a picture is impossible on account of the want of light. If there be any at all near, there is hope. It is surprising what can be and has been done by the aid of mirrors. The celebrated Dr. Vogel actually photographed some of the very remarkable interiors of the Egyptian sepulchres in this manner. They were approached by subterranean passages. At the outer end of one of these a large mirror received the sun's rays on to the mirror at the inner end, which in its turn reflected them again on to the subject. The exposures were of course long, but the end was by these means successfully attained. There is one great point in the matter of light, about which we are often very liable to be deceived. It is the great variety in the intensity and actinism of light at different times and seasons. The blue colour of the sky proceeds from the fact that the particles of air reflect blue light, the quantity varying with the hour of the day, and being strongest when the sun is highest, and diminishing as the sun sinks. Therefore, there is more actinism during the middle of the day, that is, between eleven and twelve. The power of light varies very greatly at different seasons; thus at Berlin, Bunsen found that, expressed in degrees, the chemical power of light varied as follows:—

	12	1	2	3	4	5	6	7	8	o'clock
June 20 ...	38	38	38	37	35	35	24	14	6	degrees
Dec. 21 ...	20	18	15	9	0	—	—	—	—	"

Thus we see that in winter the chemical power of light is exceedingly weak. We may also be much deceived by great brightness in the light. It does not always follow that a bright day is a chemically light day; for instance, very easily may we be deceived on a bright sunny day in February or March. These are points which, if carefully noted and considered always, would save many a negative from being under-exposed. As a last remark on natural light, I would mention its remarkable power in rendering certain substances insoluble; for instance, the gelatine, as prepared for the mechanical printing processes. We all know how the negative is placed over the pigment paper, and where the shadows are; how the gelatine, having been acted on by the light, is rendered insoluble. Apropos of this, I will just relate a circumstance in the German campaign of 1870.

In the campaign of 1870, the well-known pea-massage was one of the most important articles of food for the army, and was prepared daily by thousands. The fabrication of the interior portion caused little difficulty, but the obtaining of so many skins created much difficulty. As

* Read before the Bristol and West of England Amateur Photographic Association.

the supply fell short, a substitute was sought in vegetable parchment. This paper, which is produced by dipping blotting-paper in sulphuric acid for about a second, then washing and drying, is distinguished by its skin-like properties of resistance. It is impenetrable to water and difficult to tear; it is, therefore, used for the production of bank-notes. It was attempted to make sausage skins of this paper by doubling a sheet cylindrically and pasting it together. No glue or gum can, however, resist the effect of the boiling water in which the sausage has to be cooked, and so the artificial sausage-skin fell asunder. Dr. Jacobsen solved the problem by producing an adhesive substance, with the help of the chemical action of light, which could resist boiling water. He mixed the glue intended for the sausage skin with bichromate of potash, and exposed the glued parts to the light. This made the glue insoluble, and now the artificial skin endured boiling water thoroughly well. The number of sausage skins prepared in this way by the chemical action of light amounted to many hundred thousands.

And now as to artificial light. I will simply speak of one or two kinds. Firstly, the magnesium light used by the aid of Solomon's reflecting clockwork lamp—a capital light for enlarging negatives; the electric light, very brilliant, and most useful for lighthouses, but not so suitable for photography and the lime-light. I have used the first of these—namely, the magnesium light—as very many others have, doubtless, far more than I have, and I have found it most useful. There are many other useful chemical lights very suitable as aids to photography, the formulae for which, I presume, all present have seen given in different journals and books. For transparencies at night a very effective and actinic light will be found by using petrolene with a large proportion of solid paraffin dissolved in it. I have, with its use, successfully printed transparencies in five seconds; but light is a wide subject, and if we were to do only a little towards exhausting it, to-morrow morning would still find us occupying this room; so I will now pass on to the next subject.

(To be continued.)

ON THE ALKALINE DEVELOPMENT OF THE PHOTOGRAPHIC IMAGE.

BY CAPTAIN ABNEY, R.E., F.R.S.*

Since alkaline solutions have been introduced for the development of the photographic image, there has been a certain amount of ambiguity regarding their action. It has usually been assumed that their sole function is to reduce to the metallic state the particles of silver bromide which have been acted upon by light.

The alkaline developer consists of pyrogalllic acid or other oxygen-absorber, an alkali such as ammonium hydrate, and a restrainer such as potassium bromide. These are generally mixed together and applied to the film on which has been impressed an invisible image in the camera. Those parts acted upon by light darken under the influence of the solution; whilst, if the surface be in a proper condition and the proportion of the restrainer to the alkali be well balanced, the portions unacted upon by light remain unchanged. The image thus formed is soluble in nitric acid; and further tests show it to be metallic silver. In order to discover the part which the alkaline developer played to cause this reduction, a large series of experiments have been conducted in the laboratory of which I have charge; and the results appear sufficiently interesting to be published.

Bulbs were made of the shape shown in the accompanying figure. In A was placed, whilst carefully excluded from all light, thoroughly washed silver bromide and pyrogalllic acid. In B was placed a solution of potassium hydroxide or other alkali except ammonium hydrate. If ammonium

hydrate were required, the bulb B was made double; in the first was placed ammonium nitrate, and in the other potassium hydroxide, calculated so that the ammonium salt

should always be in excess when the potassium was brought into contact with it. The tube C was attached to a Sprengel pump; and when the apparatus was exhausted, C was sealed, and the whole of the alkali caused to enter A. After from two to sixty hours the bulbs were broken, and the solids and liquid kept for analysis. As far as can be judged, the silver bromide was instantaneously attacked by the alkaline pyrogallate.

There is no action due to pyrogalllic acid on the silver bromide without the presence of an alkali, as was proved by keeping them in contact for weeks and noting their appearance.

After a large number of experiments, it was found that the amount of silver bromide capable of reduction was primarily dependent on the amount of pyrogalllic acid present, and in a secondary degree on the amount of alkali present. Thus one equivalent of pyrogalllic acid can reduce four equivalents of silver bromide to the metallic state if sufficient alkali be present to combine with the bromine liberated. The solution, after evaporation to dryness, was found insoluble in benzole or ether, &c., and only partially soluble in alcohol. A part of that dissolved was further found to be the bromide of the alkali; and the excess of alkali not in combination with carbonic acid was also found in the solution. The amount of carbonic acid was found to be considerable, equal to one equivalent of pyrogalllic acid. (It seems unnecessary to give the analysis of the organic residue.) Apparently the compound formed is totally different from that obtained by Stenhouse* when investigating the action of bromine on alkaline pyrogallate. From the above experiment, it will be noted that the reduction of the silver is independent of the absorption of external oxygen, and that only a definite amount of silver can be reduced by a given amount of pyrogalllic acid.

When, in addition to the alkali, a large excess of soluble bromide was added to the bulb B, the same results were obtained, though the reduction of the silver bromide seemed to take a rather longer time to effect. The following is an example of the quantities employed in these experiments:—

In bulb A was placed ... 300 grains of AgBr and
10 grains of $C_6H_3O_3$;

In the bulb B was placed 300 grains of KHO

dissolved in the least possible quantity of water.

The amount of Ag found to be reduced was 33.86 grains; and the amount of KBr found in solution was 36.97 grains.

Layers of thoroughly exposed and unexposed silver bromide were next treated with a rather weaker solution of the alkaline developer; and when the restraining soluble bromide was omitted, the reduction to the metallic state took place in each layer almost equally. When the soluble bromide was present in equivalent quantities with the alkali, the reduction took place first in the layer that had been exposed to light, and spread gradually into the other layer.

* Philosophical Magazine.

* Journal of the Chemical Society, January 1876.

From this we may gather that the exposed silver bromide is more readily reduced than that unexposed, and that the solution of soluble bromide and the alkali acts less vigorously than the alkali alone.

Another point to investigate was as to the means by which the density in an alkaline-developed image was produced; for it could not be supposed that merely those atoms of silver bromide which had been reduced to the state of sub-bromide would be attacked, since the sub-bromide of silver is essentially a coloured compound, and can be distinguished even in small quantities. A plate prepared with silver iodide was flowed over with tannin and dilute albumen, and dried. It was then exposed in the camera, and after exposure half of it coated with an emulsion formed in collodion by silver bromide. Now a photographic image impressed on silver iodide is not amenable to alkaline development unless the solutions be excessively strong. An alkaline developer made as below was therefore employed—

1.—Pyrogallie acid...	16 grains
Water	1 ounce
2.—Potassium bromide ...	20 grains
Water	1 ounce
3.—Liquor ammoniac (880) ...	1 "
Water	8 ounces
or	
Potassium hydroxide ...	15 grains
Water	1 ounce

One part of Nos. 1 and 3 were added to every three parts of No. 2. As might have been expected, but a trace of an image was seen on applying the developing solutions to the uncoated iodized plate (and this trace was subsequently proved to be due to the sensitive albumen salt); but where the emulsion had been used, an image gradually appeared, not very strong, but still perfectly visible, and of printing density.

Silver bromide plates were treated in the same way: in this case there was a feeble image on the part uncoated with bromide emulsion; but on that part coated with emulsion the image appeared on the bottom surface of the emulsion film, and gradually worked its way up till reduced silver was obtained on the top surface, where the light had most strongly acted on the exposed film. The recoated half-plate, on fixing with potassium cyanide, gave a perfectly bright image, clear and dense, whilst on the other half it remained feeble.

With bromide plates in which only a feeble image could be obtained, the same procedure gave the requisite density; and this fact is likely to be of practical value.

(To be Continued.)

THE SPOT PLAGUE.

BY THOMAS M. LAWS.

Of all photographic ills, the spot plague seems to be the worst to bear, and the least understood. Many fine days' printings have succumbed to its ravages. Notwithstanding the amount of discussion and liberal treatment it has received, this great bane is constantly cropping up in various printing rooms in one or other of its many phases, if the experiences of poor unfortunates who periodically pour their grievances into these pages are to serve as index. That albumenizers are alive to its prevalence is evidenced by the recent articles by Mr. Skinner. No sooner is one species successfully explained away, before another appears, and for a time holds its sway.

During the past year, spots, blue-white, sickly-looking, broke out among our prints. This being their first appearance in any shape among us, we were completely at a loss to divine their cause.

"It's the paper," cried the printer. "No; it is the sensitizing," muttered the toner. "It must be the washing," feebly whispered the mounter. The spotter said nothing, "his heart was overcharged to express." The young apprentice (safe in innocence) ventured, with some of the worst, to the principal. "Then and there was

hurrying to and fro." "Who mixes the silver?" "Has anyone been inventing anything?" Questions like these were rapidly asked and as rapidly disposed of, resulting in the despatch of a telegram for different paper. For a while all went well, till the sample lot was used, and a new ream opened. "Any spots?" were the words that trembled on our lips next morning. "Just the same," was the dreaded answer. Time went on; various theories were mooted and freely discussed. "It is the spray sparkling on the prints directly they are placed in the trough." "No; it is that new sensitizing room—something comes from the plaster and spoils the paper." This last was indeed very feasible, for we well knew that a newly-plastered room, for evident chemical reasons, is not the place to dry sensitized paper. For awhile this put us off the right track, till getting the same spots on resorting to our old room proved it was not the cause. We then determined at every printing to use principally paper that had never troubled us, along with pieces of spotty, previously marked, and prepared and finished in different ways.

Then ("twas passing strange!"), do what we would, we could not produce a spot. This was rather annoying—all our tests, of course, went for nothing. This was the case during some very dull weather, with fewer prints than usual, which gave us the first glimpse of the cause of our trouble. Directly the weather changed, and the number of prints increased, the spots broke out.

The question now arose, "What was the difference in treatment of a small and a large batch of prints?" It was then we came to the glaring fact, that the paper received from a well-known, old-established firm could not survive even a couple of minutes over a certain time of immersion in the hypo solution. The largest batches of prints were, in our practice, left a little longer in the hypo than the others, and this was found to be the cause of the spots. If prints from this particular paper (which probably is now in general use) remain in the hypo (say) ten minutes, no spots will result; but two or three minutes more, and spots will appear while in the washing trough, and with still longer immersion they will gradually gather while looking at them in the hypo.

While recognising the great importance of the fixing of prints (which ought to be gauged as accurately as any operation in photography), yet there is no reason why such penalties should ensue by overstepping the time of immersion, and albumenizers should see to it that no paper is sent out but will admit of some latitude.

A MONSTER PHOTOGRAPH.—The *Philadelphia Ledger* describes a photograph of the exhibition grounds, which is probably the largest photograph on a single sheet of paper in the world. It was produced by Mr. F. Gutekunst. The sheet of paper on which it is printed is ten feet long, and eighteen inches wide, and special baths for the silvering and toning of this large sheet had to be made. The difficulty in the way of printing a picture of this size from seven negatives on a continuous sheet of paper is very great. The whole sheet must first be silvered. A section of it is exposed under one negative until printed, and then a second section is printed, and so on until the picture has been completed. The lines of the picture (parts of which may be found on two negatives) must be accurately joined—no double exposure can be permitted, else a dark line will show the junction of two negatives—and, finally, each of the seven prints must be made of the same depth of colour. This is largely a matter of judgment, for the pictures are always printed much darker than they are intended to appear when finished, and the time of exposure affords no certain guide to the depth of colour, because the degree and power of light change with every passing cloud and with every hour of the day. But after the printing has been completed the "toning" with gold must also be evenly done, else the blacks will be of a bluish cast in one part of the picture, and of a red tone in another part. It is, besides, extremely difficult to handle such a large sheet of paper as it passes wet through the washing processes, the toning and fixing baths, &c. There is scarcely a trace of the junction of prints, and the whole picture is uniform in colour and tone.

THE CARBON DISCUSSION.

THE discussion on the carbon process at the meeting of the Photographic Society, on Tuesday evening last, would probably disappoint many. There can be no doubt the subject is one of rapidly-increasing interest. The possible necessity of taking up the process for professional purposes is a question which all photographic portraitists of position feel bound to consider. Some few try to ignore the necessity at all; others are satisfied that they need not be uneasy at present; but the most enterprising are earnestly enquiring how they may best overcome the confessed difficulties, and get into smooth working order with the least risk and sacrifice. This question was not answered on Tuesday night. The discussion scarcely, indeed, touched technical questions at all; there was certainly no debate on many of the points of difficulty of which these in their carbon novitiate often complain.

But, whilst the discussion was less comprehensive and less technical than might have been anticipated or desired, it was in some aspects very interesting and encouraging. The especial qualification for giving an opinion of weight on such an occasion is experience, and the experience brought before the members was of an essentially encouraging character. Mr. Baden-Pritchard, superintendent of the photographic department at the Royal Arsenal, stated that they had worked the process in his department with satisfaction for seven years, and had, during that time, turned out upwards of a hundred thousand large prints, using the process as it was introduced by Swan and Johnson. The excellence of the prints exhibited gave the greatest value to this testimony.

The next definite expression of experience was that of Mr. Hughes. This was especially interesting, inasmuch as some time ago Mr. Hughes announced that he had definitely given up silver printing, and banished it and all its belongings from his establishment; carbon alone being employed in printing the pictures of an extensive business in portraiture. After a time rumours began to circulate that carbon had broken down in Mr. Hughes' establishment, and, of course, many amiable chuckles were indulged in by those who had been too wise to try it. The statement of experience from Mr. Hughes was, therefore, the more interesting and startling. He stood up in the meeting on Tuesday evening as the most uncompromising advocate of carbon who has ever before spoken on the subject. It was true that there had come troubles, unexpected, and temporarily baffling, but not inherent, and he had for a time had to resume the use of silver. Strangely enough, this return to silver produced no renewed love of the process or its results. He had never before felt so much disgust to silver printing as he did on

trying it again after twelve months' working of carbon. He now avowed his conviction that the sole difficulty in the way of working carbon was inexperience. He strongly confirmed the view we recently expressed as to the folly of any man believing that because he was a photographer he ought to be able to practice a new mode of working without going through the process of learning it. At one time he, like many beginners, complained of bad tissue and other materials. Now he knew it was bad manipulation. At one time he thought carbon could produce, with special negatives taken to suit the process, as good prints as silver. Now he knew that, with any negative, carbon could produce better prints than the best silver prints from the same negative. This is, doubtless, very strong speaking; and probably but few in the photographic community will endorse the opinion. But it must be remembered that it is based upon a trial very few have made, as experience that, perhaps, none other has gone through, and is, unquestionably, worthy of grave attention.

The one technical question which was brought before the meeting was not really discussed. Mr. Pritchard, in a brief paper, examined the common defect of carbon prints, reticulation in the material forming the image. Mr. Pritchard found that the defect could be produced by excessive desiccation of the sensitive tissue; and Mr. Sawyer's experience, that it could be produced by over rapid drying, and prevented by slow drying, was practically a confirmation of Mr. Pritchard's position. But the *dernier mot* on this subject of reticulation has not been spoken. From the various examples which have come under our attention, we fear that all the forms of reticulation and all its causes are not covered by these explanations. In the experience of Mr. Woodbury, in producing his reliefs with bichromated gelatine, the addition of some kinds of pigment produces a granulated reticulation. In the early experience of the old photo-engravers—amongst whom we may name Paul Pretsch, Dallas, and others, whose effort it was to get their exposed film of bichromated gelatine to dry with a reticulated grain as a matter of much importance in their process—one difficulty was that this reticulation always appeared with some samples of gelatine and not with others. The Autotype Company, as manufacturers of the patent tissue, have doubtless given, as it has been their interest to do, careful attention to the matter. But it cannot be undesirable, not the less, that experimenters adopt Captain Abney's advice, and in their experiments try the effect of differently-prepared tissues. In some experiments, limited by our journalistic engagements, which we tried some time ago, we found the thickness of the film of gelatine an important factor in the matter, a thick film, requiring long hanging before it was dry, always reticulating; whilst a thin film, which rapidly dried, was almost invariably free from this defect. Impure air, long keeping of the sensitive tissue, its momentary exposure to light; indeed, any cause which produced a thin, insoluble film on the surface of the tissue, incapable of expanding when the gelatine underneath it expands on immersion in the water—all these things tend, in our experience, to produce reticulation.* Other causes and cures have been recently suggested in our pages, which we cannot discuss now.

We may, in conclusion, remark that other and more technical discussions on carbon are desirable, and would doubtless prove instructive to many anxious to learn.

PRIZES AT THE EDINBURGH EXHIBITION.

NOTWITHSTANDING the controversy evoked by the determination to give medals at their exhibition on its first announcement, it is probable, we think, that the issue will give general satisfaction. In the award of such a

* Since this article was in type we have received a letter from Mr. Spenser on this subject, which seems to be in harmony with the views we have expressed.—[Ed.]

large number of prizes, after the wearying examination of such a large collection of competing pictures, it would be strange if some of the decisions were not open to challenge. There will be inevitably many disappointed competitors, who lose no honour, however, by failure, and whose work is of the highest order; but there will be none, we hope, who will challenge the decisions of the jury as either incapable or partial in their judgment. The gentlemen forming the jury of award appear to have been selected on the same principle as those composing the jury in the Crawshaw awards. In that jury was an Associate of the Royal Academy, a professional photographer, an amateur photographer, a photographic journalist, and the secretary and president of the Photographic Society, thus securing various forms of cultivated judgment. The Edinburgh jury consists of two artists, two professional photographers and an amateur photographer Sir Daniel Macnee, President of the Royal Scottish Academy, and Norman Macbeth, an Associate of the same Academy. The photographers consist of well-known men. Mr. Rodgers, of St. Andrew's, is one of the oldest of photographic portraitists, and old photographers remember that, so long as twenty years ago, Mr. Rodgers' portraits were the wonder and envy of the profession throughout the country. Mr. Annan, of Glasgow, is also well known to all photographers for the excellence of his work. Mr. Lessels, an architect and amateur photographer, is president of the Edinburgh Photographic Society. Technical knowledge, artistic judgment, and high standing were thus combined in the jury. Some of the awards and some of the omissions will doubtless create surprise—indeed, have done so already; but, on the whole, we are satisfied that the bulk of the medals are fairly earned, and will give general satisfaction. It will be seen from the report of the judges, which we print on another page, that the gold medal is awarded to a foreigner, M. Kareline, a Russian artist, obtaining it for portraiture. As this medal is awarded for "the picture which possesses the highest degree of merit, irrespective of size or subject," the award is a high honour, and furnishes an interesting commentary on the fact that at the American International Exhibition six medals were awarded to the only six Russian photographers who contributed to the exhibition. The medal for the best enamel was also awarded to a Continental artist. We may, in connection with this award, express a feeling of regret that some of the most able photographic ceramists in this country failed to contribute. The awards, generally, are well distributed amongst Scotchmen and Englishmen, and we may mention that it should be remembered, in connection with the awards, that a large number of fine pictures were exhibited which were marked "not for competition."

Critical Notices.

FAMILIAR LETTERS ON SOME MYSTERIES OF NATURE AND DISCOVERIES IN SCIENCE.
By DR. T. L. PHIPSON. (London: SAMPSON LOW and Co., 1876.)

THIS is a new and interesting work from the pen of a gentleman well known in the scientific world, who has been long familiar to our readers as English correspondent of the *Moniteur de la Photographie*. It consists of fourteen letters, which treat of the following subjects:—The *Ignis fatuus*, or Will-o'-the-Wisp; Electric Fogs; the Chemistry of the Ocean; the Science of Sleep, Somnambulism, and Anæsthesia; the Marvels of Electricity applied; Plant Motion; Firestones; Observations and Experiments connected with Atmospheric Electricity; Lightning Prints; Earthquakes; Luminous Animals; Aërolites; Life on the Earth; and Inhabited Planets.

Though written in a familiar style, these letters contain

many original observations and carefully historical details, so that the work will prove, we doubt not, as acceptable to the student and man of science as to the general public. It contains some very curious pages on certain luminous phenomena, and a complete account of the rise and development of electrical observations. As it is sure to be widely read, we need not do more than allude to it here.

SCIENCE LECTURES AT SOUTH KENSINGTON: PHOTOGRAPHY. By CAPTAIN ABNEY, R.E., F.R.S. (London: MACMILLAN and Co.)

THERE is probably no other book in existence in which the reader would obtain an account so brief, so lucid, and so comprehensive of the history and technics of photography as we find in the two lectures delivered by Captain Abney at South Kensington. Within a space of thirty-two pages every event and every detail of importance of the early history and progress of photography, including its latest phases, is given, forming a compendium as interesting to the general reader as to the photographer.

THE PHOTOGRAPHER'S ALMANAC, 1877. (D. H. CUSSENS, Southport.)

MR. CUSSENS again issues his useful little pocket almanac for photographers. Besides a calendar, &c., it contains two Woodburytype prints, illustrating some admirable accessories for the studio.

Correspondence.

VARNISHING TRANSPARENCIES.

DEAR SIR,—Your reply to "R. G.," in this day's PHOTOGRAPHIC NEWS, might mislead him or her, and many others. In my own experience I find that it is *absolutely necessary* to varnish collodion transparencies, if they are to be placed in a window in London, at least. Believing at one time as you evidently do now, I fitted some transparencies unvarnished into a window about three years ago; all those that I varnished are as perfect as they were at first, while the unvarnished ones have *sulphuretted*, and gone all round the edges, much as a Daguerreotype oxidizes when exposed to the atmosphere; but they are not cleanable like Daguerreotypes.—Yours truly,

J. WERGE.

11a, Berners Street, January 5th.

[Unless the transparency be sealed up perfectly between the glasses, it will doubtless quickly suffer in the impure atmosphere of large towns. It will, probably, be wise to be guided by Mr. Werge's experience, and varnish either with a cold "crystal" varnish or spirit varnish.—ED.]

MICRO-PHOTOGRAPHY FOR GENERAL USE.

"That place that does
Contain my books, the best companions, is
To me a glorious court, where hourly I
Converse with the old sages and philosophers;
And sometimes, for variety, I confer
With kings and emperors, and weigh their counsels:
Calling their victories, if unjustly got,
Unto a strict account; and in my fancy
Deface their ill-placed statues. Can I then
Part with such constant pleasures to embrace
Uncertain vanities?"

DEAR SIR,—In your last issue the article on "Micro-Photography for General Use" strikes me as being very Utopian, and its scheme quite as impossible now as it was seventeen years ago. In an extreme case like the siege of Paris I grant it may be—indeed, has been—turned to account; but can you imagine a student or literary man seeking his knowledge from a series of tiny rolls with a microscope?

Some ancient rolls are still shown, I believe, in the Jewish Synagogue at Hebron, but this mode of keeping

manuscripts was discarded about the year one, that is to say, nearly nineteen centuries ago. They were usually written on parchment, with the columns of reading perpendicular to the length of the roll. The ancient Greeks, and, before them, the Egyptians, had the same method, the latter people using papyrus on which to inscribe their characters; so that these rolls were in fashion when the pyramids were building. Fancy an encyclopædia, or other large work of reference (and these are specially named in the article I am criticising), being put into a roll or scroll, and you wish to consult an article under the letter A, when you find the preceding reference, made one minute before, perhaps, was at the other end of the alphabet! What an unwinding and winding up there would be! The author says, "Micro-photography will not, of course, supersede ordinary printing." I should think not. Who would like to read a micro-photographic reproduction of any author's original manuscript? Then, as to the very small cost of these tiny tomes, or volumes rather: if a rare and valuable work is to be photographed, two copies of such work must be pulled to pieces for copying purposes (for you cannot copy both sides of a leaf at once, and the pages must run consecutively in the roll), and probably they would have to be bleached and rotted to make them available for photographic purposes. Who, I ask, would trust his precious folios, quartos, or duodecimos, to undergo such usage? No doubt it would be very pleasant for the studious man to be able to carry about with him a complete library in his travelling-bag.

"The assembled souls of all that men hold wise!"

(though it might be difficult to enjoy in a railway carriage) and to get his *Times* roll with the other rolls at breakfast. But, joking apart, I am quite of the proposer's own opinion where, in his curious last paragraph, he says, "there are very great difficulties in the way of carrying out this project;" and it will be a long, long time before book-worms are seen coveting and bidding against each other for a tall copy (say two inches) of an early black-letter book "emprynted" by Caxton, Wynkyn de Worde, Tottell, or some other old typographer, and done in micro-photography and rolled round two sticks!—I am, dear sir, yours very truly,

RICHARD KEENE.

Derby, January 9th.

FILTERING PAPERS.

SIR,—As you surmise, the filtering papers introduced at Paris, and referred to in your last issue, are not new. Many years ago the late Dr. Lotheby taught his practical chemistry class the same way of making them.—Yours faithfully,

A. A. MANTELL, M.D.

CARBON PRINTING.

SIR,—“A Carbon Experimentalist” has replied to my letter. He asked for information, and he received more than he asked for. Still he is not happy, for he abuses me. The writer had asked for information as to the size and number of tanks and dishes that were necessary for carbon printing in a small commercial business. I replied that there is no common agreement among carbon printers on this subject. The knowledge how to work the process suggests to each one how he can best carry it out to suit his own wants. I said, further, that the mere inquiry for this knowledge showed that the writer wanted something of far more importance—the knowledge of how to profitably use the tanks and dishes. I recommended the writer to get such solid information, which obtained, the rest would follow as a matter of course. I therefore suggested to him that he should not fritter away his time by writing anonymous letters, but go to head-quarters, pay an honest fee for the instruction, see the work done, and go and do it himself.

For giving this advice, which I still feel to be the very best that could be given, I am abused and called a “trot-

for the Autotype Company, and the Company are called upon to repudiate this advice. I referred to “head-quarters,” because I know no other means by which this valuable information can be so satisfactorily obtained; and I recommended that an “honest fee” should be paid, because I thought that no reasonable man would expect to receive practical instruction without giving an equivalent. This correspondent is also annoyed that I allude to him as being “anonymous.” When a gentleman makes a request and signs his name, as Mr. Robinson did recently, the communication is regarded in quite a different light to that of an anonymous correspondent. But the real offence that I seem to have given to “A Carbon Experimentalist” is in recommending him to pay “an honest fee,” for he alludes to it several times in his letter. Is a “Carbon Experimentalist” one of those who wish to obtain information, which, as a business man, he will hope to turn into money, and yet objects to pay “an honest fee” for it? And does he, by concealing his name, wish to get it, not only on the cheap, but also on the sly, so that he may possibly use it to the detriment of the man who gave it?

A SUCCESSFUL WORKER.

THE DISCUSSION ON CARBON PRINTING.

DEAR SIR,—With reference to the discussion upon “Carbon Printing” at the meeting of the Photographic Society on Tuesday evening, there are one or two remarks upon the subject of “reticulation” of the tissue, which I should like to offer.

It was shown by more than one speaker how the effect of reticulation could be produced, but little was said explanatory of the cause of it. The subject is, perhaps, not yet fully understood, but the observations of M. Placet may throw some light upon it indirectly. He noted that when a film or sheet of gelatine is immersed in a solution which has a tendency to dissolve it, and afterwards into a second solution having a tanning or contracting property, the whole surface is covered with a “grain,” caused by the contraction it has undergone. He notes that the characteristics of the grain, as to thickness, form, and depth, vary according to the nature of the gelatine or other organic substance, and the liquid employed. Upon his observations he based a process of engraving by photography, for which he took out a patent in 1874.

We can readily imagine that when a streaky tissue is immersed in a solution of bichromate, especially in hot weather, or when the gelatine employed has been in a somewhat too soluble condition, the action of heated air (which always has a tendency to produce insolubility in bichromated gelatine, whether mixed with pigment or not) will, by inducing an insolubility of the surface produce the “contraction” referred to by M. Placet, and which is virtually the “reticulation” so annoying to the carbon printer.

Rapid drying was noted as one of the means of producing this effect, and if this refers to drying by heat, I fully agree with the statement; but I have met with many tissues very rapidly dried by means of cool, dry air, which have shown no tendency to exhibit this phenomenon.—Very faithfully yours,

JOHN A. SPENCER.

9, Grafton Road, West Kensington, Jan. 10th.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE usual monthly meeting of this Society was held on the evening of the 9th instant, in the Water Colour Gallery, Pall Mall, Mr. J. GLAISHER, F.R.S., in the chair. The minutes of a previous meeting having been read and confirmed.

THE CHAIRMAN called attention to the fact, that at the next meeting, in accordance with the laws, the president, one vice-president, the treasurer, and six members of council would retire from office. Members might nominate candidates, and the

balloting papers would duly reach every member. The retiring members of council were Mr. Francis Bedford, Major Malcolm, Mr. Stillman, Mr. Howard, Mr. Bird, and Mr. Hughes.

Mr. S. FRY then briefly opened the discussion on carbon printing. He referred to the prevalent instability of silver prints, and to the fact that this instability, instead of becoming rarer, seemed to be more prevalent. Carbon printing, on the other hand, had steadily been progressing, and, thanks to the method of working introduced by M. Lambert, was now a practical and possible process for the photographic portraitist to undertake. In witness of this position, he showed a large number of choice prints taken at random out of the regular produce of one gentleman who worked it regularly, Mr. Sachs, of Halifax. He also showed some transparencies produced by himself in carbon for producing enlarged negatives.

Mr. H. BADEN PRITCHARD exhibited a number of large carbon prints produced at the Royal Arsenal, Woolwich. He said they had been working the carbon process pure and simple for about seven years at Woolwich, and during that time they had produced not less than a hundred thousand prints, of the character of those before the meeting. The method they used was that introduced by Swan and Johnson, and they had not felt it necessary to adopt the recent modifications of M. Lambert. Mr. Pritchard then read a paper on Reticulation in Carbon Prints, in which he attributed the tendency to reticulation to excessive desiccation of the tissue.

The CHAIRMAN read a note from Col. Stuart Wortley, regretting his inability to be present (Col. Wortley was laid up with a broken rib and other injuries incurred in the late Arlsey collision). He stated that he had worked the Lambertype process for some time with great satisfaction.

Mr. JAMES HUGHES had been an ardent worker of the carbon process for about ten years, but it had only been comparatively recently that he had been able to work to his complete satisfaction, so as to adopt it as a substitute for silver printing. The condition he had always laid down for himself was that the process, besides being practical, should, in all respects, produce pictures equal to those produced by silver. However permanent, if it had not been beautiful, he was not prepared to accept it. In this respect it must, at least, reach the level of silver, or he would not recognise it as a legitimate substitute. The process had reached that stage. It had become practical, and the results were beautiful, and he had been one of the first to embark in its constant working. In his estimation M. Lambert was unquestionably the introducer of carbon printing into practical use in this country. When he saw this clever manipulator he was charmed by his working, and by his success when working under all kinds of difficulties. He was working from home, with other people's negatives, under all kinds of unfamiliar conditions, and yet he succeeded perfectly. Well, he adopted the process, and he gave up silver entirely, working only carbon. This went on for twelve months. Then there came some troubles into which he need not enter—but the hot weather was one of them—and he felt it necessary to resume silver. Well, if there was one thing more than another which disgusted him with silver, it was the return to its use; and he felt satisfied that only an increase of knowledge and experience in working carbon was necessary to banish silver altogether. But patience and perseverance there must be to overcome, not the difficulties of carbon printing, but its special peculiarities. One of the Editors had recently pertinently remarked that many photographers seemed to think that the mere fact of being photographers gave them some special qualification for practising carbon printing without learning it as a new business. Many of them had without a doubt acted in this spirit, and taken it for granted that the process must be wrong if they could not work it successfully at once. The truth was that previous knowledge in photography practically went for nothing. Some of those present were in their third apprenticeship in photography. In the early days of some present, the Daguerreotype process alone prevailed for portraiture. Then came collodion, and it was found that a very perfect knowledge of the Daguerreotype process was very little help to practising the collodion process. Indeed it often happened that the men not hampered by previous experience and traditions of another process succeeded best with the new process. So it was with old photographers and the carbon process. They were apt to regard tissue as a kind of inferior albumenized paper, to be dealt with in manner similar; and it had not received that attention which it required, and which it demanded as a condition of success. He wished earnestly to impress upon all working in

this direction—and he urged it for consolation as much as for guidance—that the common charge of “bad tissue” was a huge mistake, and, properly interpreted, meant simply want of experience and bad manipulation. Let them constantly bear in mind, when talking of difficulties, that the chief difficulties were want of knowledge and want of experience. Twelve months ago he believed that carbon wanted humouring, and that special negatives were necessary. Now he was convinced that carbon would produce from any negative a finer picture in every respect than the best silver print from the same negative. This was the result of his experience and observation; this being so, he felt that the public had a right to expect that photographers would furnish them with permanent pictures.

Captain ABNEY, as a carbon worker for seven years past, felt that one of the principal difficulties was not knowing the materials he was working with. He did not know how the tissue was made, nor what it was made of; and he felt that in working out a novel process such a knowledge was desirable. He would recommend experimentalists to prepare materials for themselves, and by different kinds of tissue so made they would gradually acquire some real notion of the carbon process and its requirements.

Mr. F. BEDFORD asked if the gloss he saw on the various specimens was a necessity, or an attempt to imitate albumenized paper. He thought it was in bad taste, as a fine matt surface was more artistic, especially in large work. The glaze was admissible, he thought, in small work.

Mr. PRITCHARD explained that it was not necessary; but that his men thought it the right thing, and they used their zinc plates highly polished.

Mr. HUGHES said that carbon printing admitted of every surface, from perfectly matt to the highest glaze. Popular taste at present went in for the glaze.

Mr. F. HOWARD mentioned the experiments of Mr. Blanchard and others in treating silver prints with collodion, and pointed out that such prints, so treated, showed no sign of change.

Mr. BLANCHARD said that small pictures required finer finish than large ones, and the practice of enamelling the surface gave small pictures the effect of finish. There was one point, he thought, important to notice. Modern carbon prints frequently looked heavy and dull in the shadows, whilst many of Mr. Swan's early prints were free from that fault. He thought this was due to the attempt to imitate the tone of silver prints, which rendered necessary the use of a large proportion of transparent pigment. A smaller proportion of an opaque pigment would give, he thought, a better effect, as giving a surface more perfectly reflecting back the light. He based this idea upon the reflecting qualities of water-colour drawings and Daguerreotypes.

Mr. SAWYER said that in regard to those who might be disposed to take Captain Abney's advice, and make their own tissue, he could promise an addition to their troubles they little dreamed of. He would advise them, on the contrary, to purchase in small quantities, and test carefully. He could assure them that to make a good tissue required an amount of experience not quickly gained. As to Mr. Blanchard's suggestion, he would consider it; so far as his experience went, he did not think the result would be in accordance with Mr. Blanchard's idea. In the tissue made for reproductions of engravings, a small quantity of opaque pigment was used, but no additional luminous quality was produced. The Company was, he hoped, progressive in all its work, and they were constantly striving to improve their tissue. Regarding reticulation, they could produce or prevent it at will with the same tissue. It was a matter quite in the hands of the operator. If a sensitized tissue were placed in a room to dry at a temperature which would require seven or eight hours for drying, the tissue would work without reticulation. If precisely the same sensitive tissue were placed where it would dry in half that time it would reticulate. A piece of tissue sensitized, then divided and submitted to these two modes of drying, then joined, exposed on the same negative, and developed together, would give, in one half, reticulation, and in the other, perfect freedom from it. He then referred to the troubles of silver printing during many years, and pointed out that the greatest difficulty of carbon printing were not more formidable than those attending silver printing in its early days.

Captain ABNEY said he did not recommend photographers to make their own tissue, except for experimental purposes. He thought the remarks Mr. Sawyer had made furnished the strongest confirmation of the propriety of his advice.

The CHAIRMAN commented on the interest and desirability of

the discussion, adding his testimony to the wisdom of obtaining and paying for lessons from experienced men. He (after proposing a vote of thanks) announced that a paper would be read at the next meeting, which would be partially devoted to business, partly to a paper on Photography from a Holiday-maker's Point of View, by Mr. H. Baden Pritchard. At the March meeting the Silver Bath and its Troubles would be discussed, when he hoped they would have the assistance of Col. Stuart Wortley to take part in the proceedings.

The meeting was then adjourned until Feb. 13th.

EDINBURGH PHOTOGRAPHIC SOCIETY.

An ordinary meeting of the Society was held in 5, St. Andrew's Square, on Wednesday morning, the 8th inst., the President, Mr. LESSELS, in the chair.

The minutes of last general meeting were read and approved, and Messrs. James K. Brown, John Howie, John Houlden, George Mason, Thomas R. Rodger, Jun., James Anderson, Alexander Dinnie, M. Macpherson, George Cheyne, R. Anderson, R. Middlemas, J. Geddes, Edwin Smithells, and David Gregg, were admitted ordinary members.

The Council reported that they had considered the remit made at last ordinary meeting, and begged to recommend that a presentation picture be given to the members, to be printed by one or other of the carbon processes from a negative to be selected from the pictures at present on Exhibition.

After considerable discussion, it was resolved to select one picture, and that the selection be left to the Council, the members of which were requested to enter the name and catalogue number in a book provided for the purpose, to be found on the Superintendent's table in the galleries. It was also resolved that two other pictures be selected in the same way, and supplied to subscribers at such prices as might be arranged by the Exhibition Committee.

Messrs. KEMP and Co. then exhibited an improved sciopticon, which was explained by Mr. Bashford, who used it to show a number of very fine transparencies of physiological, botanical, and mechanical subjects sent by Herr Ganz, of Brussels. The improvement claimed for the sciopticon in question is the absence of the dark line generally present on the disk of the original instrument. A number of very beautiful pictures contributed by Mr. Pillans were then distributed by lot, and after the usual votes of thanks the meeting was adjourned.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

The ordinary monthly meeting of this Society was held on Wednesday, January 3rd, at the Museum, Queen's Road, Bristol, Mr. P. J. WORSLEY, F.C.S., one of the vice-presidents, in the chair. The minutes of the previous meeting having been read by the Secretary and confirmed,

The SECRETARY handed round some pocket almanacs sent for the members by Messrs. Cussons and Co., of Southport.

Mr. DANIEL proposed, and Lieut. LYSAGHT seconded, Mr. Aldridge, of Bristol, as an ordinary member, who was forthwith elected. Messrs. Webber, Boyden, and Strachn, were elected members of council.

The CHAIRMAN then called upon Mr. H. A. H. Daniel to read his paper on "Light, Exposure, and Development" (see page 16), after which

Lieut. LYSAGHT spoke of the shutter mentioned by Mr. Daniel as not of recent introduction, being brought out by Canon Beechey some few years since.

The CHAIRMAN considered it far more advisable to get the clouds from a separate negative.

Mr. BRIGHTMAN spoke of a remark of Mr. Daniel's, as to the discolouration of Canada balsam in lenses as caused by light, and rather doubted it, and which, he thought, was pretty well proved when he once bought an old lens at a second-hand bookstall, the cement of which had greatly changed colour, but the rim of the cell had quite covered one part of the balsam, which was quite as much discoloured as that fully exposed.

Lieut. LYSAGHT upheld Mr. Daniel's assertion relative to the discolouration of the balsam often in careless eyes condemning a lens, and instanced the case of a friend of his who bought for very little money an apparently discoloured lens, when it turned out to be only the cement which was discoloured, the lens being a very fine one.

The CHAIRMAN drew attention to the very different colours different kinds of glass would turn.

Mr. DANIEL reverted to his statement relative to the assistance to development that pouring the developer off the plate for a few seconds gave, and hoped some present might throw some light on the subject.

The CHAIRMAN suggested that when the quantity of developer on the plate was reduced, as it were, simply to a thin film, the temperature of it might be raised, thereby causing the result spoken of, although quantity did not, as a rule, affect chemical action.

Lieut. LYSAGHT asked what was the result of a mixture of loaf sugar and nitrate of silver.

The CHAIRMAN said that he was not aware of any compound that would be formed thereby; certainly nothing perceptible.

Mr. WEBBER enquired the object of adding loaf sugar to the nitrate bath.

Mr. DANIEL said that he found a good sized lump very useful in causing the plate to keep moist longer, and so facilitate the production of clean negatives.

After some further discussion on the use of boracic and acetic acids in the negative bath, and a vote of thanks to Mr. Daniel for his paper, proposed by the Chairman and seconded by Mr. Webber, the meeting was adjourned.

FRENCH PHOTOGRAPHIC SOCIETY.

A MEETING of the Society was held on the 1st inst., M PELIGOT, President, in the chair.

M. PERROT DE CHAUMEUX called attention to the process of Mr. Ernest Edwards, of printing upon fabrics by means of aqueous solutions, a block being employed for the purpose, something after the manner of the Lichtdruck process; the absorbent portions, and not the non-absorbent portions, of the gelatine being, however, made use of to convey the impression.

M. LIMOUSIN showed a specimen of *glasvolle*, a material little known in France, and which was employed in Germany and Austria particularly for the filtration of liquids. He read a short note on the subject (in our next).

M. JULES GIRARD gave an account of his continued research with the microscope, and especially in connection with the phenomenon usually termed fogging.

M. PERROT DE CHAUMEUX presented the Society, in the name of the author, with a little volume entitled "Les Couleurs Reproduites en Photographie." It conveyed a description of the process of M. Ducos du Hauron, that gentleman having collected and re-edited the papers already written by himself, and issued them in this collective form.

The members then proceeded to the election of the jury of awards for the forthcoming year; the gentlemen chosen being MM. Andra, Becquerel, Chardon, Davanae, Ferrier, A. Girard, and Peligot.

M. ALFRED CHARDON exhibited some prints produced by a process modified by himself.

M. ROUSSELOU showed a photo-mechanical print produced in the printing press, which was stated to be the first specimen of its kind, namely, a photograph in half tones from nature pulled from a printing press. M. Rousselou believed the result would have been much more satisfactory had it been produced by a skilled printer.

M. ROUSSELOU also showed some specimens of photo-engraving.

M. KLERJOT, representing M. Ducos du Hauron, gave a demonstration of the latter's process. He commenced by exhibiting three *cliches* secured through the coloured screens, and then showed three monochrome prints in red, yellow, and blue obtained therefrom. The yellow and blue superposed yielded the greens of the picture, and on the addition of red the image was complete. The result created some surprise among the members.

The proceedings then terminated.

PHOTOGRAPHIC SECTION OF THE AMERICAN INSTITUTE.*

The usual monthly meeting was held November 8th, the President, H. J. NEWTON, in the chair.

The minutes of the last meeting were read and approved.

Mr. D. C. CHAPMAN said that Mr. H. T. Anthony showed him, during the week, some prints which he had recently made, and that there seemed to be some peculiarities about the colour of the negative which appeared to give a better tone to the paper prints than negatives of any other colour. He asked him if he

* Condensed from *Anthony's Bulletin*.

did not think a peculiar opacity of lights and shades in the film would not produce the same.

Two negatives with the same opacity will give quite different prints; one set will tone easier and much better than the other. This is due to the colour of the negatives. Now the question comes up, whether the colour of the negative affects the wave lengths of light on the paper; whether these going through a certain colour, changing the wave length, will not give a more pleasing tone than waves of another length. Thus sepia seemed to communicate a peculiarly pleasing character to the picture. Now, suppose we have a blue negative, all the light passing through that is blue light; and whether it is the wave length that does the work or the peculiar condition of the silver salts is a question. If we take paper and print it under red glass and then under ultramarine blue, the wave length of light in one case is nearly double the length of the other. Does this difference produce variation in the silver salt sufficiently to affect the tone of the picture?

The SECRETARY remarked that this was a pretty close calculation, and involved a problem most difficult to solve. The paper is under the negative only a short time; but under orange or red it is necessary to expose the paper a long time. A sensitive paper is subject to other influences besides the actinic light. And it is a very sharp point to demonstrate whether it is the length of exposure or the wave length which causes the variation. If it passes through a sepia negative, the action is comparatively slower. Prints taken from the same negatives in sunlight and in shade often have a very different tone.

Mr. CHAPMAN inquired whether it was the length of time or the wave length that does the work?

The PRESIDENT remarked that several years ago he experimented considerably with colouring negatives. He thought there could be no question but that different coloured negatives made prints which would give different tones, other conditions being equal. He used aniline colours in the varnish to produce the different shades. A deep purple varnish was the one which gave the most pleasing results, and it was adopted at that time by quite a number of our photographers.

The SECRETARY asked the President if he had ever given them a formula for the ground glass substitute?

The PRESIDENT replied that there was one similar to his, published, he thought, in the *Boston Journal of Chemistry*. Some one saw it and put it in the market as a secret preparation. The ingredients are benzole and ether, with either gum sandarac or gum dammar. He usually used gum sandarac. He found that a little alcohol would make it work finer; with it you can grade it to any degree of fineness you desire. The formula which he used is:—

Ether	4 ounces
Benzole	2 "
Alcohol	½ ounce

The gum is added from ten to twenty-five grains to the ounce. Care should be taken not to use too much alcohol, which would give a transparent instead of a ground glass effect. In using this preparation, the result is the same as in printing by diffused light.

The SECRETARY asked if heat was used in applying this preparation?

The PRESIDENT replied, no; it dries in the air without artificial heat and very quickly. He had frequently, in preparing a negative where the sky was thin, used what is called in the trade opaque on this surface; and by rubbing off portions of this you can make clouds to suit your taste.

Mr. CHAPMAN said that much was said of the durability of carbon prints. Now, do not our albumen prints last just as long as we want them? What is the use of having something that will not benefit the operator or his customers? He was pretty well satisfied that in the majority of cases it is found that as fashion changes new pictures will be taken. A change of fashion involves a change of dress; and people are anxious to see how they look in new costumes, and hence new pictures are desired. If all the pictures that Mr. Kurtz has taken of wealthy people were preserved, how seldom would he have to repeat them! The old negatives would not suit a new style of head gear. The carbon process may be valuable in showing the growth of a child, and in that case the first picture should be durable. Every photographer who does a general portrait business can usually judge whether a person wants a dress or a face taken. That class of people who care most for dress do not care for a carbon print. The majority of silver prints will last as long as needed; histo-

rical and astronomical, and such matters as require to be kept on record, would give way to the carbon process; but as to its introduction into galleries, he did not think the photographer or the public wanted it. Those who want to preserve their pictures are but few.

Mr. A. BROOKES desired some pictures copied by the carbon process, and he was told they would be more expensive.

The PRESIDENT said it was evident that carbon prints would be more expensive than silver ones. From a financial point of view, the photographer does not look with favour on the carbon process; that, at least, was his inference. Whether, however, it would be for the pecuniary benefit of photographers in the long run to have it generally understood by their customers that the prints they furnished them would become worthless in a few months, is a question which could be easily settled without discussion. He said he did not think it fully settled that silver prints could not be made as durable as carbon ones. The testimony of some, at least, in Europe, who have given the carbon process considerable attention, is, that they are not always permanent. Gelatine, which forms the foundation of the carbon picture, bears no comparison to carbon for durability. If the gelatine should decompose, the picture of which it was a component would suffer. He said he had seen silver prints fifteen or twenty years old that had undergone no perceptible change; such prints were not, however, on albumen paper. More care is undoubtedly required to preserve the whites with albumen paper than with plain. Card mounts not unfrequently contain destructive elements.

Mr. WEIL said that bronze is also the occasion of difficulty.

The SECRETARY remarked that he was convinced that atmospheric influences had much to do in producing this effect. Some eight or nine years ago, a friend presented to him some one hundred and fifty or two hundred stereoscopic prints. He left them in his library down town, wrapped in the brown paper in which they came; they were not in a particularly dry place. But last winter, in order to make some changes in his room, he brought them up to his present residence, and examined them. They were as brilliant as on the day they were made; he was surprised to find them in such perfect condition. Some two or three weeks ago he had looked at them, and found that now, in less than a year, they are nearly ruined, while during eight years they were not in the least affected. In the room in which they were formerly kept were hung some steel saws, and they were completely rusted. He kept in the same drawer with them a print which was sent to him about nine years ago to illustrate panoramic work. This was kept in a pasteboard case, and was not affected in the least.

The PRESIDENT said, there are some kinds of atmospheres that photographers work in that is very injurious to their work. He remembered some ten years ago that Mr. Hallett, in the Bowery, sent for him, as he was in trouble. He said that all of his plates came out of the bath with markings in the line of the dip. A new bath would work the same, and he wanted to know if he could divine the cause. As soon as he entered the room, and used his olfactory sense and optics, he at once determined what the matter was. The room was a large one, and the gas was brought from the farthest end, its entire length, to the operating sink, and this gas was carried in a rubber tube. The rubber was vulcanized, and the sulphur of the rubber combined with the hydrogen of the gas. The air was full of it, and this came in contact with the surface of the bath and formed sulphuret of silver there, which made the markings. He advised him to take the rubber down and replace it with iron pipe, which he did, and no further trouble was found.

After some further conversation, the proceedings terminated.

Talk in the Studio.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At the last meeting of this Society, a large number of lantern transparencies were exhibited by the lime light. The pictures were the works of Messrs. Brooks, York, Fernely, and other members. There was a large attendance of members and their friends.

EDINBURGH PHOTOGRAPHIC SOCIETY'S EXHIBITION.—The *Glasgow Herald* has the following on the Edinburgh Exhibition:—"Under the auspices of the above society an interesting exhibition of photographs was opened towards the end of last week in the National Galleries, Edinburgh. An exhibition of a similar description was held in Edinburgh nearly ten years ago, and

these fortunate enough to have witnessed the pictures on both occasions must have been impressed with the great stride towards perfection in the art of photography which has been made within the decade. As indicating the widespread interest which such an exhibition creates, it may be mentioned that photographers resident in nearly every part of the civilized world have sent specimens of their art to Edinburgh on this occasion. To be specific, there are pictures from India, America, the Bermudas, Germany, Russia, Hungary, Holland, France, Belgium, England, Ireland, Wales, Scotland, and the Isle of Wight and Man. Wandering through the north and south cotages and the rooms included in the National Galleries, one is struck with the large number of exhibits—the catalogue showing the number to be 1,185—the variety of subjects chosen, and the difference in the style adopted by home and foreign artists. The striking peculiarity of the pictures from countries where the atmosphere is clearer and drier than our own is their sharply-defined lines, and the strong lights and shadows which they present. When the subject treated is architecture or sculpture, such conditions of the atmosphere are of great advantage, because by their aid people who have not and cannot have the opportunities of seeing the originals, by looking at the photograph, can get a fair idea of the building or the statue represented. The Eastern collection includes ancient architecture, sculpture, specimens of Babylonian and Assyrian antiquities, &c.; while contributions from artists nearer home include portraits, studies in composition, and views of scenery in this country and on the Continent which have now become familiar to the tourist. Whether the picture be a portrait, a landscape, or composition, the highest excellence is everywhere manifest. Portraits in every style, from the carte-de-visite portrait so common now-a-days to the half-life size in oil, adorn the walls, and bear evidence to the fact that a photographer who knows how to use the material and improved mechanism at his disposal can preserve every lineament of one's features with striking fidelity in the process of enlarging. The result is equally satisfactory when the leafy trees of "bosky dell," or the serrated rocks of a wild glen in the Highlands, is photographed. In short, to the mere onlooker, the exhibition is a most pleasurable one, but to the student of photography it is one of intense interest, because not only has he an opportunity of comparing what has been and what is in photography, but also of seeing and comparing the best work of home and foreign artists. We understand that the exhibition will remain open during the month of January.

EMBELLISHMENT.—A charge of embellishment by a photographer at Hitchin, which we noticed a few weeks ago, was heard before the sessions a few days ago, when the prisoner, W. Allen, was sentenced to three months' hard labour.

ANOTHER SUICIDE WITH CYANIDE.—Dr. Hardwick held an inquest a few days ago, as to the death of Alexander George Lewinton, aged 23, a chemist's assistant. It appeared that deceased was in the service of his uncle, a chemist, in Cleveland Street. On Saturday, between nine and ten, he was found dead in bed, and a breakfast cup which had contained cyanide of potassium was on a table close to the bed. Dr. Nix, Upper Marylebone Street, who was called in, said the death took place four or five hours previously. In the right-hand pocket of deceased's coat he found a bottle containing cyanide of potassium, which had been tested. The case was adjourned for further evidence.

HOT WATERPROOF CEMENT.—The following is a valuable cement which, if properly applied, will be insoluble even in boiling water:—Gelatin, five parts; soluble acid chromate of lime, one part. Cover the broken edges with this, press lightly together, and expose to the sunlight: the effect of the latter being to render the compound insoluble.

To Correspondents

P. S. T.—A detailed account of the gelatin emulsion process will occupy more space than the whole devoted to answering correspondents. You will find many articles in the News and in our Year-Book. In our Year-Book just issued you will find an article by Mr. Kennet giving much information on the subject. If you wish to prepare your own emulsions, see articles in the News of March 16, April 13, June 7 and October 13.

W. H. LONDON.—The reaction which follows the addition of cyanide of potassium to the nitrate bath is a double decomposition in which cyanide of silver and nitrate of potash are formed; the latter, being soluble, remains in solution, whilst the cyanide of silver is thrown down as a white precipitate. When a precipitate is thrown down, other matter in suspension, and sometimes in slight chemical combination, is often thrown down also. There is no reason to fear that any soluble compound of an injurious character will be formed and held in solution in the bath.

M. MARCELIN.—We will endeavour to obtain a copy for you; but we regret that we have not one we can lend. If we obtain a copy we will forward it, and you can forward us the amount in stamps. If you have the back volumes of the News, you will find the process fully described in our Tenth Volume, August 24th, 1866, when it was communicated by Mr. Arthur Taylor, of Marcellin, the originator of the process. In the Year-Book of 1869 it is well described by M. de Constant, who worked the process admirably. Of course albumen will not do in the process, and equally of course the shellac is not soluble in simple water. To an ounce of water add 10 grains of phosphate of soda, 8 grains of borax, and 30 grains of bleached shellac. The mixture is simmered in a pipkin for a couple of hours. This evaporates the solution, which is re-dissolved in another ounce of water. To make it more sensitive, 3 grains of chloride of ammonium may be added; but, if our memory serves us, Mr. Taylor did not use this. Drawing-paper is immersed for half a minute, and when dry floated on a 60-grain silver bath. We have prints of various tones sent us by Mr. Taylor ten years ago, and also by M. de Constant not eight years ago.

X. 304.—The photographs of Mr. Bedford are to be obtained; but we cannot tell you which publisher, as you do not say which series. Probably you will obtain the prints or the information by writing to Mr. Bedford, 336, Camden Road, London, N.W. Mr. Crewdson does not publish his photographs.

F. HUDSON.—Mr. Terry's address is, we believe, 3, Mount Pleasant, Lower Broughton, Manchester. We were sorry to miss your name.

H. K.—The simplest plan for trying the experiment is to obtain an aniline violet dye, say Hoffman's purple. This is soluble in alcohol, and can easily be added to a spirit varnish, which can be applied to the glass.

J. A. B. is not, we presume, a reader of the News, or he would scarcely ask us to give him a "process to prepare a certain, simple, and rapid dry plate of good keeping quality, also means of developing the same." Probably one-eighth of our volume just completed has been devoted, as the numbers were issued from week to week, to the statement and discussion of such processes as he desires. Full details of the coffee process, about which he enquires, have been given in the same volume. That process he will find fully detailed, as well as other dry processes he will find in the Year-Book of PHOTOGRAPHY, just published at our office, price one shilling. As a novice the coffee process will probably suit his purpose well.

A THREE YEARS' SUBSCRIBER asks "if we ever heard it suggested that it might be possible to produce models as perfect as pictures in the camera?" Our correspondent is scarcely explicit enough in his query. What does he mean by "models as perfect as pictures"? An ingenious scheme of photo-sculpture was invented by M. Williams some years ago, and Mr. Woodbury has produced very good bas-reliefs by photography. You will find in the advertising columns of the News and Year-Book the announcements of manufacturers of emulsions. Whether any of them prepare the special formula you require we are uncertain. The cause was probably want of experience. Great care is required, as the plates are very sensitive, and a little carelessness in exposing them to the light, in many dark rooms, will cause fog.

G. W. M.—We have no information on the subject. We do not know of whom the inventor obtained his prism. We should think they could be produced by any glass cutter; but of the price we know nothing. The lower price you mention seems improbably small, and the other immoderately high.

FRED SUMNERSON.—The groups you forward us are very good. A little more sentiment and precision in mounting them are the chief improvements required.

AN OLD HAND.—Many thanks. We shall use some of the copy shortly.

A. L. T. HAARMAN.—Many thanks for your interesting letter and stereographs just arrived. More in our next.

ART PERIODICALS.—A correspondent, whose letter is mislaid, asks which is the best periodical or magazine connected with art. There is no technical journal of an artistic kind at present in existence. There is the *Art Journal*, *The Portfolio*, and other similar journals devoting their attention to subjects connected with art, and giving illustrations of an artistic kind, but not specially writing on points connected with the practice of any of the arts.

Several Correspondents in our next.

The Photographic News, January 19, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE CAMERA AS A PLAYTHING—THE CAMERA AS A SCIENTIFIC INSTRUMENT.

The Camera as a Plaything.—The general public, as a rule, are not greatly impressed with the exigencies of photographic manipulation. What you have to do is to cover a bit of window glass with some collodion stuff, and put it in a sort of bath, and then, having slipped the thing into the camera, you pour two or three mixtures over it, and there is your photograph; you may blacken your fingers over the job, but that's all. Most people have this idea of photography, and many a fond parent has thought fit to purchase a set of apparatus and chemicals for his boy, so that he may amuse himself with them during his holidays. And the young scamp turns out so clever over the business as to confirm, beyond a doubt, the presumption that photography is but a *bagatelle*. His father is delighted to find he was quite right when he said the boy's fingers would get black over the business, and the lad comes time after time to show the progress he has made with hands apparently that have been shelling walnuts for a month. He holds up a plate upon which the outline of some figure is dimly portrayed, and points joyously to where the eyes and nose of his victim are supposed to be. And so he goes on until mamma one day suddenly becomes aware that he has marked his shirts somewhat too indelibly, for the stains are obstinate against all attempts of soap and water to remove them; while papa finds that an ingenious attempt to manufacture nitrate of silver has been undertaken amid much fuming of acid with some of the family teaspoons. Again, there is the case of the son or nephew abroad, representing some business firm in the Colonies, or holding an appointment in India, who hints in a letter home that he would be grateful for the present of a camera, &c. The relation in England at once burns over with generosity, for will he not receive some charming photographs in return? Just the thing of all others that would make a useful and suitable present. Edwin shall have what he wants at once; and off goes the kindhearted man to purchase what is required. His ideas on the subject are rather cloudy: he thinks that you can purchase the whole affair complete something after the style of an American washing machine; you have some apparatus and things, and a few bottles of chemicals, and a printed list with directions, and the affair is complete. He does not want to bother about buying a lot of things he don't understand; he wants a shopkeeper to tell him how much is wanted for the lot. Will five pounds buy the whole affair, or say ten? In most cases the old gentleman is easily satisfied, and purchases for a round sum a collection of articles, the value of which he knows no more than an octopus. He constantly receives pounds when he ought to have obtained ounces, and in return for his money gets whole jars full of kaolin and other useful but cheap commodities, while his allowance of silver and gold is exceedingly limited. Stay, he is not to be done altogether, for he asks the shopman knowingly if there is a bath among all the requisites he (the dealer) is packing up, for the old gentleman has been told something about this particular piece of apparatus by his correspondent. The latter, to show his perfect familiarity with matters photographic, has wound up his note with the words—"I must have a bath, for it enables one to see on the spot, without returning home, whether the photograph is a success or not." Of course, the purchaser is informed that a bath forms part of the apparatus, and he departs contented, not to say delighted, at his bargain. What Edwin does with the apparatus is not very clear. Possibly he worries himself with the affair for a few weeks, and then, as he has not time or inclination to make himself

acquainted with the art, puts the heterogeneous collection on one side; or, if he determines on taking up photography seriously, he will soon acquire sufficient experience to tell him that a more trustworthy fit-out, and some study and practice, are first of all necessary before he can succeed to his satisfaction. As soon as he begins to regard the camera no longer as a plaything, there is some hope of his becoming a tolerable photographer.

The Camera as a Scientific Instrument.—Germany has determined to build a photo-astronomical observatory at Potsdam, it seems, to form part of the Astrophysicalische Institute there. At present there are but very few of these observatories in Europe; the two principal ones are that at Kew, and that at Montmatre under the direction of M. Janssen. The sun pictures of our Kew Observatory have for some time past been among the most valuable records in existence of our solar body, and have already served many scientific ends. M. Janssen's observatory, now the rival of Kew, has been erected entirely through the energy and perseverance of that well-known astronomer. It consists of a few wooden buildings, which served M. Janssen and his colleagues in Japan two years ago for the shelter of their instruments during the observation of the Transit of Venus. The structures were carried back to France, and M. Janssen, having secured the possession of them from the French Government, proceeded to erect them in an eligible situation north of Paris, on les Buttes Montmatre, a spot that has acquired a sad notoriety as the place of execution of the two French generals, Thomas and Clement, by the Communists. The Photo-astronomical Observatory at Potsdam is, we are told, to be especially fitted up for securing photographic observations of the heavenly bodies, and will thus constitute a third official establishment of the kind in Europe. There are, however, many private observatories in this country, where much good work is done, and we may refer to Mr. Huggins's paper, which appeared in these columns a short time back, to show that the study of the heavenly bodies through the medium of photography is a science that is commanding considerable attention now-a-days. But nothing has yet been done on this side of the Atlantic to rival the fine pictures taken by Mr. Rutherford, of New York. That gentleman's magnificent moon photographs, for instance, stand altogether unrivalled, and his pictures of the stars, the Pleiades, and others, are among the most successful results secured by photo-astronomy. Mr. Rutherford has, indeed, made quite a study of photography applied to astronomical observations, and has investigated the subject of collodions and developers in order to obtain the most perfect and sensitive plates for the purpose. Indeed, photo-astronomy is rapidly becoming a science of itself, for as the sensitive film yields a far more trustworthy result than can be obtained in any other way, astronomers are gradually beginning to make observations whenever possible by such means. M. Janssen, as our readers are aware, wishes to see photo-astronomical observatories established all over the country, and urges those who would further our knowledge of the heavenly bodies to make constant observations of them by means of the camera. Thus, in respect to the changes that are observable over the sun's surface, it as yet unknown whether the phenomena that we roughly designate as "spots" are all of them of the same character—that is, that while some of them may be, for instance, imperfections in the photosphere, others of the phenomena may be due to bodies passing between Mercury and the sun. This is a point, M. Janssen declares, which can only be satisfactorily solved by photo-astronomy, and it affords us, therefore, a good example of the high value of the camera in connection with the study of astronomy. There can scarcely be a doubt, indeed, that photography will, in a little while, be the recognised medium for recording observations made in this science.

ON THE ALKALINE DEVELOPMENT OF THE PHOTOGRAPHIC IMAGE.

BY CAPTAIN ABNEY, R.E., F.R.S.*

It was next proposed to ascertain in which film the developed image was really situated—whether in the exposed or the unexposed film. The double films, which had been treated as described, were taken from the glass plate by applying a damped piece of gelatinized paper to the surface; and after detachment, a similar piece of paper was applied to the surface which had been next the glass. When very nearly dry, the two pieces of paper were pulled apart; one film was found attached to one, and the other to the other. Considerable difficulty was found in this operation, and only about twenty per cent. of the whole was properly manipulated, through our not being always able to hit on the exact amount of desiccation.

In examining these films differences were observable. In some cases the image was found to lie almost entirely in the exposed film, whilst in others a strong image was obtained in the unexposed film. The difference was eventually found to depend on the alkali used in the developer, and on the porosity of the collodion in which the emulsion was formed. When ammonium hydrate was employed and a porous emulsion, the image was on the exposed film; whilst, if potassium hydroxide was employed, a vigorous image was in the top unexposed film. This can be explained through the solubility of silver bromide in ammonium hydrate. The silver bromide would be first dissolved by the ammonium, and then during the course of reduction be carried down to the reduced silver beneath it. Since silver bromide is insoluble in potassium hydroxide, the haloid would be reduced *in situ*.

Having determined this point, it was next endeavoured to ascertain if the photographic image impressed by light on the bottom surface caused a sympathetic action in the unexposed emulsion film. Plates were prepared as before, one-half being coated with emulsion after exposure, and put aside for some days. The films were then separated as described, and to each the developer was applied separately. With one or two exceptions, no image was obtained on the unexposed film. The reason of an image (always imperfect) being obtained in some cases was traced to the adhesion to it of the thin layer of albumen with which the exposed film was coated; for when the albumen was applied after exposure, no image was developed.

The foregoing experiments clearly show that the photographic image has no power of transferring itself, or of creating a sympathetic action in an unexposed film previous to development, and that, therefore, the increase of density and formation of a secondary image must be due to other action than chemical.

If further proof be required, it is only necessary to expose a dry plate, and develop it in the ordinary manner, and after drying to coat it with an emulsion, and develop again. It will be found that where the metallic silver of the first image is beneath it, there the top film develops and gives a counterpart of it. The metal exercises an attraction for the silver on the point of being reduced from the bromide in a similar way that it does when a silver tree is built up, or when a developed image is intensified by the application of pyrogallol acid and silver nitrate. There seems to be a further action, however, which must be taken into account. It has already been shown that silver sub-bromide is more easily reduced to the metallic state than is the bromide. In these last experiments I have found that there is great difficulty in starting the development in the unexposed bromide film if the layer of albumen be too thick, but that, when once started, it proceeds more rapidly. This can be accounted for on the supposition that the attracting particles of silver were too far distant from the emulsion film to exercise their attractive power.

But it seems, from other experiments which are still in

progress, that the atom of reduced silver immediately combines with the nearest molecule of silver bromide, and forms sub-bromide, which is reduced to the metallic state, and its two atoms of silver combine with two other molecules of silver bromide, and so on, the image being gradually built up in this manner. Workers accustomed to alkaline development must have noticed that the feeble image first formed in the film grows in intensity rapidly up to a certain point, and then flags: the reason of this is apparent if we consider the above re-action to take place, and the subsequent exhaustion of available silver bromide which can be acted upon.

One more experiment must be noted. If the film of albumen or gum, &c., between the two films be very thick, a reversed action will take place, which can be explained by the fact that the strength of the developing agent is exhausted in producing the image on the exposed parts of the under film, whilst on the other portions the silver bromide most readily attackable is in the upper film.

I have already indicated that this application of a film of silver bromide after exposure, either before or after development, might prove useful when employing plates which only yield a thin image when developed in the usual manner: other applications will suggest themselves. I have also previously pointed out[†] that intensity may be given to an image by alkaline development if a silver compound soluble in the alkali be gradually added to the developer. This new method, however, seems the preferable one to adopt.

LIGHT, EXPOSURE, AND DEVELOPMENT.

BY H. A. H. DANIEL.†

EXPOSURE

is a branch of photography most important, and without correctness in which all our attempts at good pictures and artistic productions are useless. I will divide this section under two heads: "when to expose," and "how to expose."

"When to expose." In taking pictures we may expose correctly, but unless we expose at the right time we are still not making every endeavour to obtain first-class pictures, and unless high-class work be every photographer's end in view, he must expect to see many pass him in the rush for pre-eminence in the art. In the matter of views, the time for exposure, of course, depends upon existing circumstances.

First and foremost, one of the matters of chief importance is the position with relation to the view in which the photographer places his camera, or, in other words, the selection and composition of the subject. You suddenly come upon a pretty bit of scenery, either near or distant, which strikes you as admirably suitable for the camera. You have only then to look at it from some different points of view, to have at once forcibly demonstrated to you what I mean. There is not one single object to which this does not apply, not even (we'll say) a pig. A full view of two hams and a curly tail would certainly not be the most becoming that could be selected; there is a proper side even to bacon. How often do we see a gentleman's house converted into rectangular elevation with sundry excrescences, instead of a range of buildings with lines pleasing to the eye, pretty grounds in front leading one's eye by easy stages to it, instead of a hard-looking house, the front almost flattening one's nose with its eagerness to at once let you know that the picture was taken for its sake. A photograph on the table, which a gentleman in the City kindly lent me this afternoon, was taken by a professional gentleman in Devonshire. He was asked to photograph the house in the distance, as it appeared from the railway. You will notice that he has given a

* Continued from page 17.

† PHOTOGRAPHIC NEWS, March 27th, 1874.

† Continued from page 24.

remarkably fine view of the rails, the roof of the intended principal object being only just visible. It will be generally conducive to artistic effect to get some agreeable object in the foreground, such as a tree, log of timber, rustic seat, and different other objects at various distances, all of which will impart a far greater degree of perspective to the picture than it would otherwise have. I also consider the position of the sun as regards the subject of great importance. No rule can be laid down, but the photographer must use his own judgment as to the position of the sun that will produce a good picture. It may be almost invariably accepted that the sun should not be in the same position as the photographer, that is to say, with its rays parallel with the lens and camera. In landscapes a side light is as a rule to be chosen, with modifications according to circumstances. In the case of a river, with trees on both sides, the chief care is to expose when the sun is in such a position that any very dark patches in the foliage do not exist, or, at least, not inharmoniously; also, that the shadows from the trees of one bank of the river do not darken the foliage of the other bank to such an extent as to rob it of its pleasingly clear definition. Clear definition must not be confounded with hard effects; most beautifully soft and yet clear definition, with atmospheric effect, may and should be obtained without any tendency to hardness. In the majority of cases it may be taken as positive that foliage is better rendered without the aid of the direct rays of the sun; in cases where water forms part of the picture it is almost always so. But very often very fine and most desirable effects may be produced by dividing the exposure, giving one part while the sun is shining, and another with diffused light. I exhibit a picture marked No. 1, which was exposed in the manner I have stated. We generally find that the lighted or partly lighted side of a landscape is taken, and, of course, in a large number of instances, it is a most suitable proceeding; but there are sometimes most beautiful exceptions to that mode of procedure. A view of the Dee, in North Wales, No. 2 on the table, you will notice is taken with the shaded side of the picture towards the camera, and I think you will admit that the effect is pleasing. But this, like many other features in photography, cannot be learnt as can a process, but requires a true artistic feeling in the photographer, strengthened by experience.

And now I will direct a few remarks under this head to portraiture. The time at which to expose is a point quite as important in portraiture as in landscape photography. Of course, it is well known that in the interest of the plate the exposure should be commenced as soon after it is put in the dark slide as possible, but there are also other matters to be equally well considered. I have always found that it is a good thing to allow the sitters some time to look at specimens and stroll about the studio or place of sitting, as that allows time for their nerves, heart, and muscles to get more composed after their walk or ride. Persons generally indulge on their way in such thoughts as, "How shall I look?" "I wonder if this sitting will do?" "Will my friends like it?" &c., &c. Now, by giving them a number of interesting photos. to examine while you prepare, their imaginations and temperaments get generally a little more calmed, and the chances are much more in favour of a good picture.

Should a friend be with the sitter I see no need of excluding him till you are about to pose, but immediately upon that, without any exception, I would urge that no one be allowed in the studio but the sitter and yourself. Prior to posing it is a good plan to get your camera focussed pretty nearly to the distance required, as every unnecessary motion during posing tends most materially to tire the sitter. Having posed the sitter it is advisable to expose as rapidly as possible, and without delay; and now will be felt the benefit of having no other little fidgets to attend to, keeping you and the sitter just when you least can do away with it. Having next to nothing to do after

posing but to expose, the time that the position and facial expression is required to be maintained is reduced to a minimum. There is one thing I would strongly deprecate, it is the custom of asking your sitter to "please look at that," perhaps a mark, crack, or dirty mark on the wall; or "keep your eyes towards that corner," very likely the visible abode of a miniature tarantula. Should you know that you are photographing a married lady, have a pleasing little coloured print or picture of a pretty child, &c. With a few different little framed subjects or models for placing in different parts of your studio, almost every sitter may have something agreeable to look at, and this is a matter greatly affecting the ultimate expression in the negative. It is not the most easy thing to continue cheerful and happy-looking while regarding fixedly a brass-headed nail, or a single painted eye peering at one, which latter I saw in a professional studio once. From the moment the posing is completed everything coming under the notice of the sitter should be pleasing and free from constraint, if a pleasant expression be desired.

Immediately the lens is uncapped, the operator should at once, by the sound of his feet, let the sitter know he has retired a pace or two, and that his eyes are not upon him, and, above all things, never let the sitter keep his eyes fixed till you are about to uncap the lens.

(To be Continued.)

TWO GOOD FORMULAS.

BY JAMES PARIS.*

If there is one thing more than another that is needed in the dark room, it is a good reliable redeveloper, one that is cheap and of good keeping qualities, and will not stain the negatives. Such a one will be found in the formula below; it redevels and intensifies at the same time, and I have used it for about three years, and have never had it go back on me once. It will cost your readers nothing to try it, and my word for it they will never go back to pyro-gallic, or silver and iron—

Protosulphate of iron	1 ounce
Citric acid	1 "
Water (rain)	1 quart

It will turn a beautiful lemon colour. For use, after washing, take as much as will flow the plate in use, and add a few drops of a 30-grain solution of silver. Be careful not to add too much, as it will make the negative harsh. I have noticed that if (after the addition of the silver) kept in the dark, it can be used again by adding more silver; but if white light strikes it, it is spoiled. I have been trying it in place of pyro-citric acid and silver to intensify albumen transparencies; have not tried it enough to form any opinion yet, but it gives a very rich brown tint. Will report again.

A Good Collodion.—Now I think I hear some one say, Here is another formula for collodion! Well, there is, and if over a year's trial of it is any recommend, I can give it that; and I must say I have never used anything better for white drapery or velvet (black), or both together, and for fineness of detail. It works quick, and will keep as long as you want; the older it gets the better. I have seen some that was six months old, and almost as white as plain collodion. It is good for both indoor and outdoor work:—

Alcohol and ether (pure con. sulph., eq. parts)	1	ounce
Iodide of cadmium	...	5 grains
Bromide of potassium	...	2 1/2 "
Chloride of calcium	...	1 grain

Bath 40 grains, slightly acid. Developer, from 15 to 20 grains strong. In mixing the collodion I usually dissolve the iodide and chloride in the alcohol, and the potassium in a little water, and add to the above; then

* *Practical Photographer.*

ie cotton, and shake well; then add the ether a
at a time, shaking well between each addition. Let
and settle. Before using, take out what you want to
nd add a few drops of tincture of iodine.
haps the above will not work exactly right under
light, any more than any other formula, so you must
the proportions of the iodine and bromine and cotton,
not the chloride, and use judgment in mixing it. Try
nd see if it is not all I claim for it.

PHOTOGRAPHIC IMAGES OBTAINED BY MEANS OF ASTRONOMICAL LENSES.

BY M. A. ANGOT.*

It has been remarked for some time past that the photo-
graphic image of an illuminated object is dilated by reason
of the luminous parts trespassing upon the black ground.
Hence M. André's recent researches upon diffraction, that
gentleman having discovered phenomena of the same order
in observing heavenly bodies through the telescope; he
charged me with the investigation of the matter so far as
photography was concerned, and I have now the honour to
submit the first part of my work to the Academy.

The nature of my experiments consisted in taking, under
various circumstances, a photographic image of a luminous
source, formed by two rectangles, separated by an interval
of darkness. The augmentation of dimension that is
observed for each luminous rectangle is equal to the diminu-
tion of the dark space between them. The sum of the two
quantities should, therefore, be constant, a mode of verifica-
tion which gives the degree of approximation in each
experiment.

The images were taken by means of a photographic
lens which the Transit of Venus Committee were good
enough to place at my disposal. The lens had an aperture
of 13 centimetres, and was rendered achromatic by the
separation of the two glasses of which it was composed; it
had a focal length, in my experiments, of about 3·80 metres;
1-500th of a millimetre measured upon the image corresponded,
therefore, with 0·109. The lens and the luminous source to
be photographed were placed in one of the cellars of the
École Normale, at a distance of 87 metres from one another,
a distance which rendered necessary the great focal length
of my lens. Finally, the photographic images were measured
with a micrometer scale, also the property of the Transit of
Venus Committee. By neglecting some of the precautions
employed in measuring the images of the Transit, I am
enabled to shorten materially the time necessary for the
measurements, and I confined myself to estimating to the
1-500th of a millimetre, which was quite exact enough for
my purpose.

The main point is, that the dimension of the photo-
graphic image increases materially as soon as you augment
the duration of pose or the intensity of the light. This
increase is such that in the circumstances under which I
operated it surpasses 0·2 millimetres in ten seconds. As
examples, I submit herewith the measurements of seven
images obtained successively upon one Daguerreotype plate,
and in the production of which no change has been effected
beyond lengthening the duration of the exposures.

Duration of exposure.	Dimensions in 1-500th of millimetres			Total. l+d
	of the luminous rectangle.	of the dark interval.		
10 seconds ...	593·5	192·6	...	786·1
30 " ...	618·5	168·6	...	787·1
40 " ...	624·0	163·6	...	787·1
1 minute ...	632·6	155·2	...	787·8
2 " ...	645·7	141·4	...	787·1
4 " ...	656·4	130·0	...	786·4
7 " ...	673·8	113·4	...	787·2

The unit in these calculations is, as I have said, the 1-500th

of a millimetre, which corresponds to 0·109, and the
column l+d, in which the numbers should be constant,
show that the mean error is about 0·001 millimetre,
or 0·005.

The phenomenon is exactly the same if you operate on
dry or wet collodion, or if you vary the intensity of the
light and allow the exposure to remain constant.

The first explanation that strikes one is to suppose
an approachment of the photographic action from one
point to another, an approachment which should increase—
like the numbers above mentioned—with the intensity of
the light and the duration of pose. If such an hypothesis
were correct, the dimension of the image would be smaller
upon an ordinary plate than upon another which has been
exposed for a brief while to the light before receiving the
photographic impression. In the last case, in fact, the
action, having commenced, should continue more easily.

To assure myself of this, I exposed to light, first of all,
one half of each plate, and then made with the two halves
a series of experiments in pairs, giving the same duration
of exposure and intensity, so that all the circumstances
under which they were taken might be identical, with the
exception in the one series of the preliminary exposure
to light. The experiment was repeated a great many times,
and always gave results contrary to those supporting the
theory of an approachment of the photographic action. I
need only quote the following numbers:—

1. Iodised and Bromised Daguerreotype Plate.

Duration of exposure.	Dimensions of the image	
	in the part exposed first of all to light.	in the part not exposed.
30 seconds ...	514·9	535·6
1 minute ...	537·3	560·4
4 minutes ...	563·0	681·5

2. Upon a Dry Collodion Plate.

Duration of exposure.	Dimensions of the image	
	in the part exposed first of all to light.	in the part not exposed.
Intensity { 1 minute ...	584·5	622·7
1. { 2 minutes ...	620·5	641·6
Intensity { 1 minute ...	516·5	558·0
about ½ { 2 minutes ...	558·5	579·0

I have not yet finished the determination of some measure-
ments of images taken upon wet collodion; but they
certainly confirm the above results.

The images, therefore, taken upon plates that have
received a preliminary exposure to light are always *smaller*
than upon those which have not seen the daylight—a good
proof against the hypothesis that there is any approach-
ment of the photographic action. The phenomenon is to
be explained on purely physical grounds; and this is what
I shall attempt at an early opportunity when I have been
able to study the laws according to which the dimensions of
the images vary with the duration of exposure, the intensi-
ty of the light, and the diameter of the lenses. I shall sho-
how all these laws—as also the effect of preliminary
exposure—may be deduced from the ordinary theory
diffraction in the focus of a lens.

NOTE ON GLASWOLLE.

BY M. LIMOUSIN.*

GLASWOLLE is calculated to render valuable services
pharmaceutist and chemist. It might be termed
wool very well, or glass silk, and it is a product en-
in Germany, and more particularly in Austria, for
purposes in the laboratory.

The *glaswolle* which I purchased during a recent
the Rhenish provinces was very finely spun gl
may well be likened to fine silk in its appearanc
is fused, and then spun on hot metal cylinders
at a considerable rate; it is only Bohemian glass

* *Bulletin de la Société Française.*

* Read before the French Photographic Socy

that can be employed for the purpose, and hence the trade is in a very few hands. Examined under a microscope, the threads of this substance are as tenuous as cotton or silk threads. They are resistant, but break more easily under a strain; they are remarkable for their extreme suppleness. At first sight it is impossible to believe in the mineral origin of the material, so much does it resemble silk or cotton fibre.

In the Austrian laboratories it is employed for filtration by putting a small quantity of it, in the form of a plug, into a special kind of funnel, which has a cavity to receive the substance. But such an arrangement in the funnel I myself have found to be wholly unnecessary, for the superior density of the glass over cotton-wool permits it to remain at the exit tube of the funnel.

By reason of its inalterability, which is the same as that of the best crystal glass, the substance presents great advantages for the filtration of acid and alkaline solutions, even of a concentrated nature, as well as of other substances, such as nitrate of silver, albumen, collodion, &c. Photographers, therefore, I believe, will be able to make good use of such a method of filtration.

Owing to the smoothness of the fibres and the absence of all capillary action, the liquids are not prevented from penetrating, by a close matting of the *glaswolle*, in the filter. Moreover, it does not possess the disadvantage shared in by all paper and fabric filters, of absorbing the liquids under filtration; neither does it absorb aromatic compounds dissolved in distilled water or alcohol. It is much preferable to amianthus, which, by reason of its parallel fibres, will not permit of its being inserted into flexible bulbs, and which has, moreover, the defect of allowing particles to float away with the liquid.

In chemical analysis *glaswolle* is particularly useful for several reasons; among others, that filtrate attached to them can be estimated with more ease and accuracy than is the case when collected upon filter papers which have to be burned.

As a final application of this *glaswolle*, I may mention its adaptability in the fashioning of glass pinchers for employment with the chromate and nitrate of silver bath, and also with iodine tinctures, &c.

The *glaswolle* is rather expensive, and may be estimated at about forty centimes per gramme; its excessive lightness, however, allows one to construct a large number of filters from this quantity; indeed, a gramme would last a chemist or photographer a very long time indeed, if he took care of the substance and cleaned it well after every operation, washing it thoroughly in plenty of water, and drying it spontaneously in the air.

[This fine glass wool is employed in many chemical laboratories in this country.—Ed. P. N.]

CARBON TRANSPARENCIES ON GLASS.

THE method used by the Autotype Company in preparing transparencies by single transfer is described by Mr. J. R. Sawyer in a letter to Dr. Vogel, who embodies it in his recent correspondence with our Philadelphia contemporary. Mr. Sawyer says:—

"At first we have to prepare the following solution:—30 grains of gelatine, soaked some time in 500 cubic centimetres of water (cold), and then dissolved under slight warming. To this solution (continually stirring it) is to be added as much of a solution, composed of 2 grains chrom-alum in 30 cubic centimetres of water, as is necessary to keep the gelatine mixture thick and dough-like. Then we have also to add, with continual stirring, as much lead vinegar, by drops, until the mixture becomes liquid again; it must be kept moderately warm. With this

gelatine liquid, using a camel's hair brush, we then proceed to brush a carefully cleaned glass plate, on which the pigment picture shall be put, all around the margin about one centimetre broad, and let it dry. After that the plate is to be slightly warmed, laid horizontal, and the gelatine solution poured entirely over it, in which case a brush may also be used, when necessary, to divide it regularly. This must be dried again, which will have to be done with the utmost possible care to keep the dust off; also during the further preserving of it. In this manner we may prepare a large number of plates, and keep them ready, for their durability is of an unlimited extent.

"After the sensitized paper is taken out of the copying frame, the margins of the same are to be bent up a little, so that it forms a kind of bowl or saucer, in which is to be poured thin, normal collodion, in the same manner as in pouring over a plate. This paper, which was previously toned, and then collodionized, is to be hung up in a dark place for drying. As soon as this takes place, it is necessary to soften, in the usual manner, this copy in water, and bring it together under water, layer on layer, in the closest contact possible, with a gelatinized glass plate, which has also been in water some time, carefully avoiding air-bubbles, dust, &c.

"After that we have to take the plate out of the water, and give both the layers a still better connection by means of the squeegee, and then let it all rest from about five to ten minutes; after that time we may develop in the manner already known by means of warm water, and the result, after a careful observation of these directions, will be an excellent one."

NEW METHOD OF PRECIPITATING GOLD FROM OLD TONING BATHS.

BY FRITZ HAUGK.*

AFTER the toning bath has done its duty, I filter it into a white flask, render it alkaline with some bicarbonate of soda†, and add, by degrees, so much of a concentrated alcoholic "aniline-red solution" as will render the liquid the colour of raspberry syrup. After this I put the bottle for six or eight hours in a well-lighted window. At the end of this period, the gold still remaining in solution will have become precipitated in the form of a dark violet powder (sub-oxide of gold), and the superfluous liquid has become colourless. The latter I pour away as useless, and so carefully recover the precipitate. After every toning operation, I filter the liquid which has been used, and put it into the same bottle immediately upon the precipitate formerly obtained, and then proceed as before.

In this way I secure, after a time, a sufficient quantity of sub-oxide of gold, and I then collect it on a filter, and wash well. I then dry the filter and filtrate, and burn them. The ash and residue is then dissolved under the influence of a slightly warm temperature in an excess of aqua-regia; the solution is afterwards diluted with some distilled water, and the undissolved residue filtered off. The gold solution secured in this way I then evaporate, and the residue is very nearly chemically pure chloride of gold. The slight impurity with which it may be contaminated by the ash of the filter is scarcely worth mentioning.

On the walls of the flask in which the gold toning solutions are collected there is found in time a gold mirror. When this has become pretty thick, it should be removed, which may be done by rinsing the bottle with a little aqua-regia, the latter being rinsed against the walls of the bottle, which is put into warm water for a little while. In this way the deposit of gold is quickly dissolved.

TONING WITH CHLORIDE OF PALLADIUM.

THE question of employing chloride of palladium in lieu of chloride of gold for toning has been again raised by our Paris contemporary, the *Moniteur de la Photographie*. M. Ellerbeck, in a communication to that journal, gives his experience of employing this costly salt for intensifying transparencies after fixing. The tint it imparts is a rich black one; but beyond this the palladium salt possesses the advantage, according to M. Ellerbeck, of not acting upon the half-tones if permitted to remain in contact with the photograph for a considerable period. The palladium acts in the capacity of a redeveloper, M. Ellerbeck says, strengthening the image and invigorating as well as darkening its tone.

In treating transparencies with chloride of palladium solution, they are rendered more suitable for the lantern and such like purposes. The collodion image, after fixing, must be thoroughly washed to remove every trace of the solutions that have been employed in developing and fixing; as otherwise the palladium will be precipitated in a metallic state, or in the form of sulphide. The strength of the solution recommended is one part of chloride dissolved in twenty parts of distilled water.

Palladium, as our readers are aware, occupies a position in regard to cost midway between platinum and gold; but there is so little demand for its salts that, in this country at any rate, they are much more expensive than those of gold. About fifteen years ago we received some fine examples by our American Correspondent at the time, Mr. F. F. Thompson. In carrying out his instructions we found the chief difficulty was a tendency to produce a cold black; and the salt was, moreover, very costly. M. Ellerbeck states that the chloride of palladium can be purchased in Paris for one franc fifty cents a gramme; and under these circumstances its employment, probably, would hardly be more extravagant than that of chloride of gold. In this country, however, the palladium salt is much more expensive, and may set down at £6 per ounce, or, in other words, at double the price of chloride of gold. Whether the results obtained by palladium toning are so advantageous as to warrant this increased cost we are not in a position to say; but until the salt is obtained at a more reasonable rate in Great Britain, its practical character will stand in the way of its general adoption.

M. LAMBERT AND CARBON IN THE UNITED STATES.

THE introduction of carbon printing amongst American photographers, under the auspices of M. Lambert, appeared to be a great success, if we may judge by the fact that the majority of the leading photographers have become licensees, and many of them write enthusiastic expressions of their satisfaction with the results they obtain. Mr. Rulofson, President of the United States National Photographic Association, having obtained a licence when in New York, tried the process himself on return to his home in San Francisco, and at once telegraphed to secure the entire licences for the State of California. We find the names of men like Kurtz, Napoleon Sarony, Gutekunst, Notman, Bendann, and many more of the distinguished and leading portraitists, not only amongst the licensees, but emphatic in their praise. A series of six silver medals and six bronze medals, for the best examples of different processes included by M. Lambert in his licenses, has been offered to the licensees, the exhibition to be held this month. American photographers are paying one hundred and fifty dollars in gold (about £30) for the use of the five patents taken out by Swan, Johnson, the Autotype Company, and M. Lambert, which cover the operations in carbon printing as at present worked.

A noteworthy fact we find mentioned, regarding which English photographers would like further information. From the statements of M. Lambert and his licensees, it appears that in the United States they have been able to work without difficulty during the hottest summer. When Mr. Rulofson took his lesson the thermometer stood at 102° Fah. And this, M. Lambert says, was effected without the aid of ice, cool cellars, or special ventilation. At the present season this question is not one of moment to carbon printers in this country; but when summer returns we shall ask M. Lambert, on behalf of many English carbon printers, to tell us how he avoids the difficulty generally experienced, and prevents the undue softening and running of the gelatine on the tissue.

As an example of the correspondence on the subject, we extract the following letter from the *St. Louis Practical Photographer*. Mr. J. W. Wykes, writing, says:—

"In August last I was in New York, and my attention was called to the pictures then on exhibition at Messrs. Anthony and Co.'s, and produced by the said processes, and I must say that the work was so far superior to anything I had anticipated, that I could not resist the desire I felt to know more about the means employed in producing such effects. I had no money to throw away, but had a little to invest, if I could see a fair prospect of a return and I have always found that it pays to be in advance in photography, and this looked to me like a step in the direction. I was told that it could not be worked in hot weather, and other objections; but as it was then the hottest time in a very hot city, I thought it a good chance to test the process. So I went in, and although the work was so intense that I could scarcely endure it—being—the picture came out as fine as though it was the favourable time. After returning home, I at once put it in competition with silver in my gallery, and to-day it is absorbing all my best work, and would do so if I did not make such a distinction in the prices as to the two processes.

"The question is asked in certain quarters, W. the man who has invested in these processes has discarded the silver for carbon? I take pleasure in saying that I am one of the men that has done so; as I consider my interest to do so, and for the season; but by making silver prints for cheap work the two classes of trade, and give my customers work at an advanced price, and it is appreciated by the public. I am glad to know that a goodly number of the best workers in our cities have taken an interest in the truly great improvement, which is to remove the stigma from the photographic art—the fading—and place it upon a permanent basis for the future."

SHOWING PROOFS OF PORTRAITS.

THE system of showing proofs from three or four negatives is, doubtless, one of great advantage to the sitter, inasmuch as one of several portraits may be infinitely more satisfactory in expression, position, and individuality, generally, than the others, each of which may be equally good as a photograph. But the system is fraught with much trouble to the photographer, and, in some cases, degenerates into a serious tax. In some cases, several negatives are retouched, in order to send out proofs from each, and these proofs are not unfrequently, in spite of rules to the contrary, retained by the sitter. The system of sending out proofs at all is of doubtful advantage to the photographer, and should, at any rate, be governed by precise conditions. Such negatives as meet the photographer's own approval should alone be sent out; the word "specimen" should be prominently written, perforated, or stamped on each, and the return of all, selected or unselected, should be made imperative. A correspondent of the new American journal, writing on this subject, says:—

"The photographic art has been very much hampered by customs which have almost become laws. One of the greatest is the showing of proofs. It is only reasonable to suppose that an artist who has devoted a lifetime to his profession, and having acquired a thorough knowledge of it, is a judge of a picture if good or bad. Then why should he submit his work unfinished to the public, whose judgment upon pictures is questionable? for the showing of proofs only amounts to this: 'Is my work good or bad? If you decide bad, I will do it over again.'"

"Now, in all other professions or trades, if we give an order for a piece of work, it is not submitted to us until finished; and if we were to criticise during its progress, we would be gently told it is unfinished."

"In my opinion, the showing of proofs is humiliating to a man who understands his business. In most cases pictures would be satisfactory when finished, but as proofs are condemned, which occasions so many instances of work being done a second, and even a third time. If the public were made to understand that whatever they ordered would be final, it would abolish the continual experimenting at the expense of the photographer, which makes our business as discouraging."

The Editor, Mr. Fitzgibbon, adds:—

"The above remarks on the showing of proofs is from one of the best photographers in this country, and we think he has struck the right chord. Abuses will naturally get into the profession, as well as improvements. The proof system, when first introduced, was in a measure intended to gratify the tastes of the parties in regard to expression; but now there is no end to the requirements wanted and fault found with the elastic photographer who tries to suit the tastes of many that have no taste at all, and who do not know really what they want; and for the want of some good reason, fault is found with good work—the style of dress, posing of the sitter, arrangement of hair—and, not to offend his patrons, he indulges them, until he finds there is no end to the troubles and labours he has brought on himself in trying to accommodate them. Do away with proof-showing altogether, and you will sleep sounder at night."

COLLATERAL ADVANTAGES IN PRELIMINARY COATINGS OF ALBUMEN.

In the very early days of the collodion process, the use of a preliminary coating of albumen on the glass plate was proposed and tried—successfully and continuously in everyday practice by some; unsuccessfully, and therefore only briefly, by others. Many photographers who tried it, and were charmed with the improved character of the negatives it aided in producing, gave it up with regret and reluctance, because, in a short time, the silver bath got out of order, and the plates began to fog.

Why some photographers succeeded and some failed in using the same materials, was not clearly made out at the time, but an examination of the question in the light of after-experience suggests that success was probably due to the use of dilute albumen, as failure was doubtless due to want of dilution. Pure white of egg, in some cases, and in others diluted with three or four times its bulk of water, constituted the preliminary coating then employed. The revival of the practice a few years ago was effected under different conditions. Very dilute solutions of albumen were recommended, and one ounce of albumen in forty ounces of water is now a common preparation for preliminary coatings. Whilst this is sufficient to secure the multitude of advantages which are found to attend this preparation of the plate, it gives, at the same time, immunity from risk of spoiling the silver solution, or causing any tendency to fog. We are not going to discuss its advantages or disadvantages in relation to the cleaning of plates here. That is satisfactorily done by Mr. Hughes in our YEAR-BOOK just issued. To many who found it difficult or almost impossible to secure subordinates who could or would really clean a plate, the boon offered by albumen as a preliminary coating was invaluable. To those more fortunate, who never had any trouble with dirty plates, the question has naturally possessed but little interest. But there is another phase of the question, regarding the use of such preliminary coatings, which possesses interest for every one. An interesting communication, from a gentleman who had many years' experience as a printer for the profession, points out the great advantages in stability in negatives which have been so treated. Indeed, he regards a negative which has not received such preliminary coating as absolutely unsafe. Mr. F. E. Elliot, with whose name as an able and experienced photographer most of our readers are acquainted, writes as follows:—

"The preliminary albumenizing of glass plates is one of the most valuable inventions of the day, as I do not consider any negative safe for any length of time that has not had such a treatment; it has saved me pounds in the preservation of negatives from the ill effects of damp and heat, when left in the printing-house, and where I used to lose numbers from the bulging reticulation, I now never lose one; in fact, I have had frames accidentally left out in the rain, and the negative swamped, and when formerly it would be all over with the plate, now after a wash with perhaps a slight touch of weak cyanide, the negative is as right as ever. Again, I have just compared several plates that I have taken some thousand copies off: those that I had not albumenized, and which are no worse than plates I have printed when with my late partner, Sedgfield, of negatives by Bedford, England, and others for book illustration, are worn out and full of spotty holes; the albumenized plates are as perfect as ever. I should say for carbon printing, which is more horny than all paper, it is almost a *sine qua non*."

The hints here given are well worth pondering.

QUALIFICATIONS FOR AN OPERATOR IN AMERICA.

A CORRESPONDENT who spent some time as an operator in the United States sends us the following amusing letter, which he received in answer to an application for an engagement in a portrait establishment. The writer says:—

"DEAR SIR,—Since writing to you, I have come to the conclusion that I now have a boy with me actually too young to leave his mammy yet; and in absence of any lines from my friend Capt. R—, I will take the liberty to propound to you the following questions, trusting that you will not get your back up:—

"1st. Have you ample experience in making the Bon Ton with the multiplying instrument?"

"Are you sure *pop* with *Babies*, and do you really understand Photography?"

"Are you willing to make pictures *Early* and *Late* as pictures can be made?"

"Can and will you *Get up and get in a reel*? and, further, can you keep cool in *hot* weather, and let your *hair* grow?"

"Please answer as many of the questions as you think proper at the earliest moment. Also please ask Capt. B—— whatever you may wish to know about me, and ask him if he will please say his say about you, and oblige yours in haste, J. O."

"P.S.—One more, and I have expired. Will you get your Stamps every Saturday Evening, and make yourself generally useful as well as ornamental for so doing?—Truly yours, J. O."]

EDINBURGH PHOTOGRAPHIC EXHIBITION.

(SECOND NOTICE.)

We are glad to learn that, great as has been the expense of bringing together and exhibiting such an extensive collection of photographs, there is every probability of the Exhibition being a commercial success. The public interest is daily on the increase, and it is a pity that the requirements of the Royal Scottish Academy compel it to be closed to-morrow. The medal awards having been published, considerable interest is being given to the successful pictures, and although it is not in the nature of things that the decision of the judges should meet with universal approval, it is satisfactory to know that the dissentients are very few.

In landscape photographs the Exhibition is very rich. If there are any who still have a doubt as to the suitability of dry plates for the very highest class of work in this direction, they have only to look at the exhibits of Mr. Wm. England to have the doubt dispelled. Hung together are six charming views in Switzerland, Italy, and Savoy, so soft, yet full of brilliant detail, and most perfect gradation, even when, as is generally the case, such difficult combinations as summer foliage and snow-clad mountains are included. Where all are so excellent, it is difficult to particularize; but we may mention "Monk and Eiger from St. Beatenburg" (No. 767) as a work of rare merit. The foreground is the bank of a lake, with finely-grouped trees on the right and left, and a few well-arranged figures in the centre. The middle distance includes groups of grand mountains, whose shadows are more or less indefinitely mirrored on the bosom of the lake, and, rising high behind all, are the beautiful snowy peaks so well known to travellers in the district. Almost equally fine, and on a much larger scale, are the pictures of Mr. Henderson, of Manchester. They are from collodio-albumen negatives, and rival the best wet collodion work in all good qualities. "A Trout Stream" (No. 287) is a somewhat difficult subject admirably rendered. On the right is a richly-wooded hill, nicely balanced by a tower of a half-hidden church, and in the foreground a rippling stream broken up into many pools, which would be the delight of a disciple of the Waltonian school, while a little higher up there is a pretty fall or weir, the water of which is beautifully transparent. Much less ambitious, but technically perfect, are several landscapes by Mr. H. A. H. Daniel, of Bristol. No one will grudge him the well merited medal. He seems to revel in quiet nooks and corners, and if such subjects present fewer difficulties in their execution, he amply makes up for it by the perfection which he has attained. "The Cascade" (No. 722) is an exquisite bit of work. Thoroughly pre-Raphaelite in treatment, every leaf and branch is so sharp and well-defined, that they might be used as illustrations of botanical lectures. In the centre of the picture is a cascade, a fine water-fall, on a rock, and breaking up into beautifully

Mr. Alexander Henderson, of Montreal, contributes eight thoroughly characteristic pictures of ice scenes on the St. Lawrence, Montmorenci, and Niagara. In "Ice just Going" (No. 594) we have an example of the ticklish work a photographer will undertake to catch what his fancy may induce him to covet. The view is from St. Helen's Island in the St. Lawrence, and includes the city of Montreal, and its mountain in the distance. The adventurous photographer has planted his camera on one of the huge blocks of ice which accumulate during the winter months, and there is unmistakable evidence that the break-up is already begun. But, with the hardihood born of familiarity with such scenes, several figures are posed on some of the masses, comparison with which conveys a tolerably correct idea of the size of them.

Cloud effects, always difficult to get, and often much misused when got, are well represented. Prof. Piazzi Smyth, Col. Wortley, and Mr. Benjamin Wyles, of Southport, all show good work; "Cloudland" (No. 657), by the latter, is a frame of four prints, the negatives of which would be invaluable to any printer of landscapes. Mr. John H. Morgan, of Clifton, also shows some really good work; quiet in tone, and somewhat wanting in contrast, it is, nevertheless, characterised by very careful treatment and excellent composition. "The Mountain Pass" (No. 1060) is a good example. The immediate foreground consists of the furrowed banks of the stream, or, rather, the bed of one, and so indicating the dry summer season. A quaint old bridge is in the centre, and, right and left, as quaint a cottage, and a spur of a mountain in pretty deep shadow. The middle distance consists of a well-defined mountain, or hill, and the extreme distance is a mountain on which there is a fine play of light and shade, and peculiarly fine atmospheric effect.

The Edinburgh amateurs come well to the front. Mr. Pantou and Mr. Muir have both got medals for really excellent work, and Messrs. Crichton, Mathieson, Pillans, and several others, are not certainly far behind. The latter, in a frame of sixteen small prints (No. 867), includes one of Lake Monteith and one of Tontallan Castle, that, both for composition and general treatment of light, are very commendable. Mr. Crichton has a frame of nine clean, crisp prints (No. 587), of which "Loch Lubnaig" is the best, and, for general effect of atmospheric distance, is all that can be desired. Mr. Edwin Smithells, of Barrhead, sends a number of well chosen views, the best of which is his "Head of Loch Katrine" (No. 575); and Mr. Mathieson is equally fortunate in his bits of "Old Edinburgh." In his frame No. 642, the "White Horse Close," one of the most picturesque remains of a bye-gone time, is most picturesquely rendered.

Our space, however, is now exhausted, and a notice of the portraits must stand over till next week.

FRENCH CORRESPONDENCE.

SIMPLE PLAN OF TESTING STRENGTH OF SILVER BATHS—
M. POITEVIN ONCE MORE—SELF-PRINTING OF FUNGI—
APPLICATION OF METHOD TO PHOTOGRAPHIC PRINTING—
M. SCOTTELLARI'S SYSTEM OF ILLUMINATING STUDIOS WITH VIOLET LIGHT.

We have just received from M. E. Boivin a note touching the analysis of silver baths which will, no doubt, be interesting to the readers of the PHOTOGRAPHIC NEWS. Of all the methods employed to discover the nature of silver baths made use of in photography, our correspondent asserts that the most convenient and economical is the one he describes. Into a flask or glass vessel graduated in centimetres, from 0 to 25, for instance, is poured to 0 the necessary quantity of the undermentioned liquid, namely:—

Distilled water	...	1,000 cub. cents.
Chloride of sodium (dry)...		6-60 grammes
Bichromate of potash	...	1 gramme

Into a test-tube is put two cubic centimetres of the bath to be analysed, and it is then sufficient to pour in drop by drop the above saline mixture. There is formed in the first place a purple precipitate, which soon becomes white by oxidation of the liquid. The experimenter then turns to the graduated vessel, to see how much of the liquid has been expended to bring about such a result. The figure revealed gives exactly the weight of nitrate of silver contained in 100 cubic centimetres of the bath submitted to analysis. According to M. Boivin this plan of analysing the silver bath is much preferable to that of employing an argentometer, which never gives one the proper weight of nitrate of silver in the bath, because the latter becomes charged after a time with a considerable amount of chloride and iodide salts resulting from daily work, which may erroneously be calculated as silver salts.

And now there is grand news to be told. M. Poitevin has appeared once more upon the photographic horizon. The learned and fortunate experimentalist, to whom photographers owe so much, has for the past ten years completely renounced photographic investigation, and cast on one side those labours which have earned for him so honourable a name. Living retired in a little town of the department of Sarthe, where he had been nominated Mayor, he passed his life as a tranquil landowner, far from the struggles and disputes of the scientific world. Now, however, an unexpected circumstance brings him back to the world which he believed to have abandoned for ever.

M. Poitevin had often remarked that certain fungi or mushrooms (*agarics*) after they had arrived at a certain stage of maturity, when placed upon a plane surface of marble or glass, left behind them, after a few hours, a very clear image of their leaves, &c., in half tones. This image was formed by the coloured dust between the leaves which falls upon the surface on which the fungi had been lying. M. Poitevin tried to reproduce the same effect, but under more favourable conditions. He experimented with sheets of glass, or paper stretched very evenly over glass, and having placed the fungus upon this surface, covered it up with a glass shade to prevent the surrounding air having an effect upon the fall of the dust. After an interval of five or six hours, he obtained a very clear impression of the leaflets. The image was not in any way stable, for the dust did not adhere to the paper, and was disturbed on the slightest friction. At the same time, he succeeded in fixing the image by employing a varnish made by dissolving a gum resin in alcohol or essence, a method which he afterwards abandoned for a better plan of operating. At present he makes use of a sheet of paper prepared with gelatine on one side only; he puts this sheet upon a plate of glass, gelatine face uppermost, and having moistened it with a brush, spreads the sheet flat with the same means. The film of gelatine is in this way moistened, and the superfluous moisture having been removed, the mushroom or fungus is put upon it, the leaves downwards. If the fungus is light and small there is no necessity for suspending it, but otherwise it must be removed at some distance from the sheet, as the leaves will get folded and the image will not then be distinct. M. Poitevin suspends his fungi by means of little supports made of thin metal and thread, from the centre of which the mushroom hangs. The whole is covered up by a glass shade, and the formation of the image allowed to proceed for five or six hours according to the season and the quantity of pollen contained in the fungus. At the end of this time the shade is removed and the fungus carefully lifted off the paper, and the result is upon the gelatinized paper, a most perfect image which is fixed as soon as ever the paper is quite dry. The same fungus will furnish successively three or four impressions. Some of the fungi are brown, violet, yellow, &c., and they yield prints of these colours. In the case of the lighter colours, such as yellow and white, they are reproduced upon gelatine tinted of a sombre colour.

M. Poitevin has illustrated this communication of his by a print of the edible mushroom, which has at first rose-coloured leaves that afterwards become brown after some days. The colour seems to be quite permanent so long as the impression is kept from the damp. M. Poitevin thinks that the process might be turned into a method of photographic printing, and in this wise:—Upon a metallic fabric or very fine silken stuff is produced a cliché, in which the parts corresponding to the whites will be impermeable to the dust or colouring matter, while the black and half-tones allow the powder to pass in direct proportion to the intensity of the tones of the design to be reproduced. M. Poitevin has promised to make some experiments in this direction, and to communicate to us the result.

M. Scotellari, who has seen the article published in the PHOTOGRAPHIC NEWS, upon illuminating with violet light, of the 5th of January, has written to ask me to say that the experiments therein detailed are incomplete. M. Scotellari urges the readers of the NEWS to make further experiments, and he mentions one which is within the power of all. Let a ray of sunlight penetrate through an opening in the shutter into a dark room; then interpose in its passage a prism, and there will be thrown upon a screen, placed at a suitable distance, an image coloured after the manner of the rainbow. By substituting for the screen a sheet of sensitized paper, or any other surface sensitive to light, the experimenter will be convinced at once of the superiority of violet light in regard to its chemical action. We may add that the experiments to which M. Scotellari invites all photographers desirous of practically appreciating his system continue from day to day, and that the results obtained are always in favour of his mode of lighting. We shall have occasion to come back to this subject.

ERNEST LACAN.

A BELIEVER IN SPIRIT PHOTOGRAPHY.

BY J. J. T. G.

THE old man came to have his photograph taken—beyond mistake an old man from the country. "What will you charge me for taking out my picture, sir?" "Half-a-crown."—"Nothing less?" No; that is the lowest price for a single carte."—"Well, you see, sir, 'tis for a little girl of mine that's in America, and she's been writing to me for it these three years, so I had to come at last."

Assistant shows some specimens. "Which style would you like?" Old man from the country takes one up, looks closely at it for some time, then, "Yes, that is nearly like; but I haven't a white waistcoat."—Proprietor: "Oh! that's not yours, you know; yours will be like you, and the clothes the same as those you wear." Explanation is apparently satisfactory, as old man from the country takes out his money and pays. "Will I get it now, sir?" "No; say in three or four days."—"Thank you, sir," going away quite contented, till the assistant runs to call him back: "Why, you haven't sat at all yet; please step upstairs to the gallery. This way, sir."

In due time the negative is taken, and old man descends, and is about to depart, when an idea suddenly occurs to him. "My old woman wears a brown dress, and a white cap, and a plaid shawl across her shoulder. She is about my own age. Couldn't you put her in this picture alongside me?" After a good deal of persuasion, we succeed in convincing the old man from the country that as we do not possess a "spirit licence" in photography, we cannot possibly photograph the invisible, and that if he wants the "old woman" taken, she, too, must visit the studio.

So he went away, but I fancied that there still lingered in his mind a feeling that if we liked to oblige him, we might have put the "old woman" in as well.

MICRO-PHOTOGRAPHIC RESEARCH ON COLLODION.

BY M. JULES GIRARD.*

In examining, under a very powerful microscope, a negative developed either by means of sulphate of iron or pyrogallie acid, it will be remarked, nearly always, that in the clear and non-impressioned parts there are crystals uniformly spread over the whole surface, having a measurement of scarcely 100 of a millimetre. These crystals of iodide of silver, which are sometimes exceedingly abundant, constitute what is termed fogging in a plate, and are the cause of many failures. They are often spread over the whole of the sensitive surface, like a cloud that light cannot penetrate. I have the honour to forward to the Academy of Science a micro-photograph of these crystals, enlarged to 300 diameters; it has been secured from a clear portion of a landscape negative, where the so-called fogging was imperceptible to the naked eye.

The effects which are produced in the sensitive film appear to be distinct from those taking place in superficial reduction. In examining the blacks or parts impressioned by the light, in the case of a series of progressive tones, it will be seen that they are formed of incrustations of a reticulated and granular texture—which is more accentuated the more the sensitive film has been acted upon by light—and that they have no appearance of granulation.

BLUE PRINTS ON PAPER, WOOD, ETC.

BY T. C. ROCHE.

THE following method gives fine blue prints on paper, wood, canvas, &c., and only requires washing to fix properly:—

First Solution.

Red prussiate of potash	...	120 grains
Water	...	2 ounces

Second Solution.

Ammonia-citrate of iron	...	2 ounces
Water	...	140 grains

The solutions should be made separately, and, when dissolved, mixed and filtered; then pour it into a dish, and float plain photographic paper on it for three or four minutes. When the paper is dried, it will keep for months. Print in the sun for eight or ten minutes; then simply wash the paper under the tap with running water. The result will be a strong blue picture on a white ground. The addition of a little gum-arabic water to the above solution, when made, will render the colour of the picture richer and the whites purer.

Correspondence.

PREVENTING DISCOLOURATION OF THE PRINTING BATH.

DEAR SIR,—I have tried various methods of purifying the printing bath when discoloured, and also of preventing its discolouring, for I found it such a nuisance being always obliged to purify, filter, and strengthen the bath. I found that though kaolin answered the purpose, it was troublesome and wasted silver, as also does permanganate of potash. At last, when about to give it up as a bad job, I hit upon the following formula, and which (if I may use the expression) I have found quite a blessing:—

Nitrate of silver	...	40 grains
Nitrate of soda	...	20 "
Ammonia	...	2 drops
Methylated spirits	...	2 drachms
Distilled water	...	1 ounce

* Read before the French Photographic Society.

I float the paper upon this bath for about three or four minutes. When I have finished sensitising my paper, I pour the solution back into the bottle, and next time it is perfectly clear and ready for use. I seldom filter the bath, as it does not require it; and I only occasionally add a few crystals of nitrate of silver and of nitrate of soda. I have been using my bath every day for a very long time, and it is now just as clear as when I first made it. It saves a very great deal of trouble, and does not waste silver, and the prints are finer in tone and quality than when I was always purifying my bath with kaolin, which I sometimes had to do after using it only once. I should, therefore, strongly recommend photographers to try this formula, as they would find it a great comfort, as well as economical. I keep my sensitised paper between sodaic sheets, and I should recommend others to do the same. I have tried citric acid and other methods; but I found them all more or less failures. Hoping this may be of use to others, I am, yours truly,
R. N. P.

COLOURING PHOTOGRAPHS IN PASTEL.

DEAR SIR,—Crayon painting, or painting with pastel colours, although more subject to injury from friction, is, I consider, very appropriate for colouring photographic enlargements executed in the style of vignette sketches, especially as the colours are applied dry; they are not likely to be affected by entering into chemical combination with the photographic substratum. Here, also, the shadows and drawing of the photograph will not be hidden unless a highly finished and complete painting in crayons is made; even then the photographic base will be found of great service. As sketches, I know of no style so easily executed by those whose artistic ability may not be great; of course, taste and facility of execution are required in all works of art, of however humble a description, to make them pleasing and agreeable. The paper of which the photograph is printed for this style of painting should be what is termed crayon paper, that is to say, paper having a rough surface or tooth, so that it may bite and retain sufficient of the crayon to produce a solid appearance.

The photographic print should be, in all cases, mounted upon the canvas properly strained on its frame as it is to remain when finished, for it is utterly impossible to mount a crayon drawing without the greatest risk of injury; neither can it be set without lowering its tone—i.e., the colours of the painting cannot be made to imbibe sufficient of any gummy or gelatinous substance to cause them to adhere to the paper and resist friction. Your readers will readily understand that crayon paintings should be so framed as not to touch the glass. The mount, or mat, in the case of smaller pictures, serves this purpose; but for larger productions the frames should have a double rabbet—in fact, it would be better if this sort of frame were used more generally; but it would prove more costly, as the glass must be first secured to the frame and the picture, either mounted on stout cardboard or frame. There is a style of painting, I believe, but little used, termed encaustic or wax painting; it is extremely durable, and I should think, by ingenious modifications, fine effects, resembling oil paintings, might be produced.

In this style, the shadows and drawing of the photograph would be necessary to form the foundation of the picture. The colours might be applied both back and front, and be assisted, in some cases, by the use of oil colours. The photograph should be printed upon strong paper, and strained on a frame without canvas or any other support, before painting it. Transparencies can be executed in this style for windows and fire screens with beautiful effect.—I am, dear sir, yours truly,

JAMES MARSH.

"PICKING UP" THE CARBON PROCESS.

SIR.—Will you allow me, as a constant reader of the *News*, to protest against the style of correspondence of which we have had some recent specimens in your pages, filling space which could be better occupied? Like most other portraitists at the present juncture I am interested in working carbon, and when I read the letter of "A Carbon Experimentalist" a few weeks ago, I looked eagerly for the replies. I am sorry to say that I was disappointed. An anonymous writer, styling himself "A Successful Worker," taunts the "Experimentalist" with writing an anonymous letter, and instead of giving the information which a successful worker may be supposed to possess, gives advice which is not asked for in place of such information. He also advises all who are in the same position as the experimentalist not to imagine they can "pick-up" carbon printing without paying for lessons. Of course there is justice enough in this. If information is worth having, it is worth paying for. But it is a fact, nevertheless, that in photography almost every distinguished man has "picked up" all he knows, without ever paying for a single lesson. The progress of photography, as we are constantly told, has been chiefly due to the free intercommunication of ideas in the journals. Is it good taste of this unknown self-styled successful worker to try to burke the system upon which the progress of photography is based? If, being successful, he is unwilling or unable to give information, let him not stand in the way of others who might do so, if they did not risk mixing with quarrelsome company. If your pages are to continue open to the enquiries of students, and the replies of the experienced workers, they should be closed to those who are more disposed to snub than to help. In hope of faring better than the first experimentalist, may I ask an answer to his queries, as

ONE ANXIOUS TO LEARN.

PS.—Will you allow me to express my deep thanks to Mr. Titcomb, and many such as he, willing to help, as well as able to work?

Talk in the Studio.

A NEW PHOTOGRAPHIC JOURNAL.—Another monthly journal devoted to photography has just been issued in the United States, under the title of the *St. Louis Practical Photographer*. It is conducted by Mr. J. H. Fitzgibbon, a practical photographer of upwards of thirty years' standing, and Permanent Secretary of the National Photographic Association, U.S. Mr. Fitzgibbon has been for many years a frequent and able contributor to photographic literature, and his first number promises exceedingly well. It is fresh, independent, and practical in tone, and whilst it abounds with good contributions (of which we give some examples in this issue of the *News*), the impress of the Editor's mind and intelligence pervade the whole number. A fine portrait of the Editor accompanies the first number, presenting a face which is at once shrewd, kindly, and manly. There is great room for such a journal in the States, and we wish it every success.

THE CONFERENCE.—The correspondent of the *Daily News*, writing from Constantinople, states that the members of the Conference have been photographed in a group by Adullah Freres, of that city, and that the likenesses of all the members are admirable.

LIFE-SIZE DIRECT PORTRAITS.—Reviewing the progress of the year, as illustrated at the Centennial Exhibition, the *Philadelphia Photographer* says:—"The most striking improvement—or departure from recognized practice—was the exhibit of Mr. J. B. Kent, of Rochester, N. Y., in which were portraits from life on negatives three feet or more in size, made direct, and printed by 'contact.' Mr. Kent has not yet condescended to tell us how this was done." Our readers will find some details of how it was done on p. 468 of our last volume.

PHOTOGRAPHY IN COURT (Robinson v. Worden).—A case of some importance to employers and assistants was recently heard in the Marylebone County Court. The plaintiff was a young professional photographer who advertised in the *PHOTOGRAPHIC NEWS* for a situation as assistant operator. The defendant, Mr. T. Worden, of Præd Street, answered, and references having been furnished, plaintiff entered into a five months' engagement. At the end of the second day the defendant intimated that he should not require plaintiff any longer. Plaintiff then brought an action for breach of contract. After some adjournments, the case came for hearing, when Mr. A. H. Bool, of Warwick Street, Pimlico, a former employer of plaintiff, gave evidence in favour of his competency. The defendant producing no witnesses to the contrary, his Honour gave judgment for the plaintiff, damages at £10 10s., with costs.

PHOTOGRAPHS OF THE SPECTRA OF VENUS AND A LYRAE.—Professor Henry Draper writes from New York as follows, under the above heading, to *Nature*:—"Since the spring of 1872, I have been making photographs of the spectra of the stars, planets, and moon, and particularly among the stars of a Lyrae and a Aquila, with my 28-inch reflector and 12-inch refractor. In the photograph of a Lyrae, bands or broad lines are visible in the violet and ultra-violet region, unlike anything in the solar spectrum. The research is difficult, and consumes time, because long exposures are necessary to impress the sensitive plate, and the atmosphere is rarely in the best condition. The image of a star or planet must be kept motionless for from ten to twenty minutes, and hence the driving-clock of the telescope is severely taxed. During last summer I obtained some good results, and in October took photographs of the spectrum of Venus, which show a large number of lines. I am now studying these pictures, and have submitted them to the inspection of several of my scientific friends, among others Professors Barker, Langley, Morton, and Silliman. There seems to be in the case of Venus a weakening of the spectrum towards H and above that line of the same character as that I have photographically observed to take place in the spectrum of the sun near sunset."

A SOLAR DISTILLERY.—M. Mouchot, whose steam boiler, heated by the sun's rays concentrated by a concave mirror, was described not long ago, recently exhibited to the French Academy of Sciences a new apparatus whereby by solar heat he distilled excellent brandy. The mirror was but 19.5 inches in diameter. A little over a quart of wine was placed in the boiler, and brought to boiling for fifteen minutes by the concentrated rays. The alcoholic vapour entered a tube placed in the centre of the boiler, traversed the supporting foot of the mirror, and descended into a room, where it condensed. The liquor was of remarkably good flavour, free from the disagreeable taste of alcohol peculiar to that obtained from wine in the usual way, and savouring strongly of the best cherry brandy. M. Mouchot afterward placed flowers and odoriferous leaves in his boiler, and made a variety of perfumes and essences. Finally leading the steam into a cooking apparatus, he prepared an entire dinner by the agency of the sun's heat.

PRINTING LEAVES.—In a recent article on "Nature Printing" the *Garden* describes various methods of obtaining copies of flowers and leaves from the objects themselves. The following, which is simple and easily tried, may be of interest to some of our readers:—"By those who have access to a laundry roller press, or an ordinary copying press, the following method of direct printing may be adopted: The best paper to use is ordinary wove paper without water-marks, such, in fact, as is used for book printing. Those who can afford to be luxurious may use thin drawing paper. First select the leaves, and then carefully press and dry them. If they be placed in a botanical press, care must be exercised not to put too great a pressure on the specimens at first, or they will be spoiled for printing. An old book is the best for drying the examples to be used; then get a small can of printer's or proof ink, and a small leather dabber, which can be bought for a few pence at any shop where wood engravers' materials are sold. Take a bit of ink about the size of a pea, and work it on a small piece of slate or glass with the dabber until it is perfectly smooth; a drop or two, not more, of linseed oil will assist the operation. Having worked the ink perfectly smooth, give the leaf a thin coating, being careful to spread it equally, not to dab it on in blotches, or the clear effect will be lost. Having applied the ink, take a sheet of paper of the size required, and lay the leaf ink down-

wards upon it, placing it between the leaves of an old book which must then be subjected to a moderate pressure in a copying press, or passed between the rollers of the washing machine. If a press be not at hand, lay the book on the floor and stand upon it for a few seconds, an operation which answers the same purpose. Impressions can be taken with greater rapidity by this process than by any other, and a very little practice will enable anyone possessing ordinary ingenuity to succeed in producing them. Soft book paper is the best for the purpose, and, previous to using it, place a few sheets between damp blotting-paper, which causes it to take the ink still more readily. At first you will find that you lay too much ink on the leaf, which then produces too dense an impression. After a little practice you will know how much ink to lay on each description of leaf. If you find the impression too black, use the leaf once again without inking it. If the midrib of the leaf be too thick, so that the part near it does not come into contact with the paper, it must be shaved down with a sharp knife. Composite leaves, as of the umbelliferae, should be divided, and their parts printed separately; other details will soon be learnt by practice."

To Correspondents.

BACKGROUND.—When a distemper background gets seriously stained with wet, the best remedy is recolouring, as it is difficult to repair a portion without showing the marks of junction. Wash the whole first with a clean brush, and then apply fresh distemper colour over the whole.

B. D. A.—The advertisement to which you allude had reference to a special mode of lighting only, and to providing roof and side lights to suit studio to order. It did not consist of a studio complete. The question as to the advisability of erecting a temporary studio, with a view to its eventual removal, is one upon which we cannot advise; it must depend so much upon local circumstances. Probably a local builder will aid you best.

BRIERLEY.—It was scarcely wise, in making wooden vessels for holding silver and other delicate solutions, to apply red lead to the joints; for if the black or white varnish with which the inside of the wood is treated wear off or chip off, and expose any portion of the lead, it will act injuriously. Pitch or paraffine is found best for the lining of a wooden bath. The varnish of collodion and linseed oil, which we have occasionally recommended in the News for treating wooden dishes, should be applied over paper, with which the wooden tray is first lined, to cover all cracks and joints. For toning, we should advise you to use a white earthenware dish, as a degree of strict cleanliness is required with the gold bath which could scarcely be seen in anything but clean white earthenware. Your bath and dish for fixing may be tried without much fear. 2. Your quarter-plate lens will probably serve your purpose for card portraits for the present, and the negatives may be taken on quarter-plate glasses, taking them, of course, of proportions suitable for card portraits. The simplest and cheapest form of printing frame will answer your purpose. Any dealer in photographic materials will supply you. You will understand their use without difficulty. The negative is laid in the frame with its glass side outwards; the sensitive paper, being dry, is laid with its face in contact with the face of the negative, the back placed upon the paper, and fastened. The back of the negative is then exposed to the light, and printing begins. When you think it is nearly done, you open one-half of the back of the frame, and examine the actual progress of the print. The other half, being kept fast, prevents the paper moving from its true position on the negative. Quarter-plate printing frames will, of course, suit your purpose.

A. B.—We fear that we cannot help you to a remedy. It is probable that, in any case, the matter would simply stand as a debt. The announcement you suggest could not with propriety appear.

J. M. STORR.—Thanks for the suggestion. We frequently do so when any information of general interest is under attention; but very many of the queries are essentially personal in their character. Even when various readers wish for similar information, there is often something special in its precise bearing which renders a detailed answer to each desirable.

NATHANIEL SYDNEY.—The powder process is valuable for many purposes. It is excellent for reproducing negatives; it is very useful for adding backgrounds to negatives, and otherwise improving them. It is excellent in the hands of an artist for producing prints on paper, or on opal glass. You will find various articles on the subject in our volume for 1874, and in our YEAR-BOOK for 1875. As to how far it will serve your purpose to learn the process, you will be best able to judge.

R. D. F.—The proportion of any resin to be used in making varnishes depends much upon circumstances. For a moderately thick varnish from forty to fifty grains per ounce of solvents; for a thin varnish from twenty to thirty grains. Some resins produce a more limpid varnish than others, and admit of the use of a larger proportion of resin, without making the varnish too thick. We do not counsel amateur varnish making, because the selection of resins and solvents, and their proper mixture, requires much experience, and failure is often a serious matter.

J. H.—We have no doubt that if published the card would sell. It is very pretty.

H. M. (Amateur).—The lantern slide you forward has not, we think, been toned at all. It is the colour often produced by developing with pyrogallie acid. A solution containing two grains of pyrogallie acid and thirty minims of acetic acid in an ounce of water will give a similar tone. Bath and collodion should be in good condition, and exposure sufficient. An emulsion plate, with a thin image brought out by alkaline development, and redeveloped with above and a little silver, would give you a similar tone. A grey image may be brought to a similar tone by bi-chloride of mercury, followed by sulphide of ammonium very dilute. 2. Collodion transparencies which are mounted under glass need not be varnished; but, if you prefer it, that known as "crystal" varnish answers very well. 3. We are not sufficiently versed in the prices and relative qualities of magic lanterns to advise. The selection we should recommend, but it is not very cheap. Your negative has been posted. It was cracked when we received it.

W. COLQUHOUN.—Many thanks. The colour is excellent.

Several Correspondents in our next.

METEOROLOGICAL REPORT FOR DECEMBER.

BY WILLIAM HENRY WATSON, F.G.S., F.M.S.

Observations taken at Braystones, near Whitby, 36 feet above sea-level.

Date.	BAROMETRIC PRESSURE.			TEMPERATURE IN THE SHADE.			REMARKS.
	Morning.	Noon.	Night.	Morning.	Noon.	Night.	
1	29.12	29.06	28.97	47°	49.5	49.5	Rain a.m. and p.m.
2	28.97	28.90	29.01	46.5	49	48	Rain a.m. and p.m. Very windy at night
3	—	28.57	28.40	52	53	49	Rain all day. Very windy
4	28.26	28.35	28.28	53.5	53	49	Rain a.m. and p.m.
5	28.58	28.50	28.52	46	50	49	Rain p.m.
6	28.58	28.63	28.90	44	50.5	46.5	Rain afternoon and night. Very stormy
7	29.00	29.10	29.19	48.5	50.5	39	Rain this morning
8	29.47	29.57	29.87	39	46	48	Fair and sunny
9	29.37	29.60	29.97	46	46	44	A little rain a.m. and p.m.
10	29.60	29.79	29.75	46	48	47	Rain p.m.
11	29.70	29.65	29.50	45	46	46	Fair, but very gloomy
12	29.18	29.20	29.27	46	49	45	Rain morning and evening
13	29.35	29.35	29.40	34	42	40	Showers this afternoon
14	29.39	29.38	29.56	42.5	44	42	Fair but gloomy
15	29.56	29.50	29.48	42	48	41	A little rain this evening
16	30.40	30.42	30.40	45	46.5	44	Showers all day
17	29.38	29.34	29.20	45	46	44	Showers all day
18	29.09	28.96	28.97	42.5	45	45	Rain a.m.
19	28.84	28.80	28.63	42	44	45	Showers a.m. and p.m.
20	28.45	28.40	28.46	41	43	41	Rain a.m. and p.m.
21	28.48	28.45	28.50	42	43	40	Rain a.m. and p.m.
22	28.65	28.70	28.83	37	40	38	Fair, but gloomy
23	28.90	29.00	29.10	38	34	36	Fair but gloomy
24	29.15	29.29	29.30	32	36	38	Stead morning and afternoon
25	29.41	29.50	29.63	30	38	34	Fair and sunny
26	29.62	29.60	29.51	30.5	32	35	Very windy. Heavy snow-storm at night
27	29.20	29.18	29.10	39	46	46	Rain a.m. and p.m.
28	29.21	29.18	29.27	46	54	45	Rain a.m. and p.m.
29	29.37	29.32	29.06	43	46	47	Showers a.m. and p.m.
30	29.16	29.20	29.08	45	51	45	Rain all day
31	28.70	28.70	28.78	51	53	49	Heavy rain with wind a.m. and p.m.

Summary.				Mornings. Noons. Nights.		
Highest temperature observed	55°	58°	45°
Lowest	29°	31°	29°
Mean	43°	46°	44°
Mean of all observations	44°		
Number of days on which rain fell	26
Number of fair days	6
Number of fair days gloomy	4
Number of fair days sunny	2

NOTE.—By referring to the columns of barometric pressure it will be seen that it was exceedingly low on the 4th, and that during the month the barometric pressure was very variable. The mean temperatures are so considerably above the average for the month of December.

The Photographic News, January 26, 1877.**PHOTOGRAPHY IN AND OUT OF THE STUDIO.****PHOTOGRAPHY AT THE MILITARY STAFF COLLEGE.—MORE PHOTOGRAPHIC PUBLICATIONS.—PHOTOGRAPHIC POISONS AND THEIR ANTIDOTES.**

Photography at the Military Staff College.—Most of the European Powers, as our readers are well aware, avail themselves of photography in connection with military affairs. In this country there are three establishments intimately connected with the art—at Chatham, Southampton, and Woolwich, and in France, if we may judge by the productions exhibited at the last Photographic Exhibition held in Paris, the art is cultivated to a no less extent by the Ministry of War of that country. In Russia, Austria, and Portugal, military photography is well known; and although Germany has no official establishment of the kind at Berlin or elsewhere, still that military nation was not slow to appreciate the aid that photography can lend to the soldier upon occasion, and at the outbreak of the Franco-German war a staff of photographers was at once organized, which successively did good and valuable work in front of Strasburg and Paris. In this country we have recently gone a step further, and have included photography among the subjects taught at the Military Staff College at Sandhurst, officers who prove themselves to be proficient in the art receiving an extra certificate. The Staff College is established for the instruction of officers who may desire to qualify for staff appointments. Officers in any regiment may compete, and a score of the most proficient are chosen as students. These remain at Sandhurst for two years, during which period they have the advantage of studying under a staff of qualified professors, and at the end of their term of study, if they show sufficient knowledge of their duties, they receive certificates of qualification, and are eligible for appointments on the staff. Such appointments are naturally enough regarded as great prizes by all young soldiers, and there is usually a very spirited competition for admission to the college in the first instance. There are of course certain subjects in which all students must satisfy the examiners; they possess a thorough knowledge, but beyond these qualifying subjects, there are others which the student may take up of his own choice, and pass an examination in. Among these voluntary subjects is classical photography, and we find that it is one which is eagerly embraced by students. A knowledge of photography is considered of so much importance, that its cultivation is encouraged by the Horse Guards as much as possible. For reconnoitring purposes, for mapping, and for illustrating military reports, the camera is of the greatest assistance, and thus it is very desirable indeed that staff officers should have some acquaintance with the art. At the last examination of students quitting the Staff College, we see that out of twelve officers who were examined in voluntary subjects, four proved to be well grounded in photography, and to have obtained certificates to this effect. Thus we are told that Capt. Grover, R.E., passed "a good examination in photography, and a very good examination in geology and experimental sciences." Capt. Lloyd, 76 F., "a very good examination in photography;" Capt. Money, 87 F., "a good examination in photography;" Captain Murray, 89 F., "a good examination in French and photography." We believe that in this respect Great Britain is in the van, and that our army authorities are the first to recognise the utility of photography so far as to encourage a study of it among staff officers. Dr. Atkinson, F.R.S., who is the professor of chemistry at the Staff College, has given the practice of photography considerable attention, and for some time past has afforded demonstrations in the art; but it is only recently, as we have pointed out, that the military students have been permitted to take photography for one of the subjects of their examination.

More Photographic Publications.—According to the *Athenaeum* we are to have two more photographic publications of importance, which will be published respectively by Messrs. Sampson Low and Co., and Messrs. Proctor and Co. *Street Life in London* is to be the title of one of these periodicals, and it is to be issued under the auspices of John Thomson, F.R.G.S., and Adolphe Smith. The idea is, to present those interested, with a series of pictures illustrating London life, and each part is to contain three photographs, printed, we suppose, by the Woodburytype process. We hardly see how such a periodical can possibly live a long time, for street types in London are not very numerous, or, at any rate, such as would interest are not, and therefore the task of portraying London street-folk must soon come to an end. The other work is to be called *The Portrait*, to appear weekly at a shilling per number. It will contain a series of portraits, also, we presume, printed in permanent pigments; among the earlier portraits published will be those of the Earl of Beaconsfield, Mr. Swinburne, Mr. William Black, Mr. Woolner, B.A., General Tcherniaeff, M. Tourguenief, &c. According to the prospectus issued, the periodical will "illustrate the time we live in by means of photographs and memoirs of those who adorn or disgrace it," so that we may expect to see the portraits of notoriety as well as celebrities in its pages.

Photographic Poisons and their Antidotes.—Although it is impossible, perhaps, for photographers to bear in mind all the antidotes corresponding to the poisons they daily employ, still, with a very little trouble, they may fix in their memories a few simple facts which might help them in instances of accidental or intentional poisoning. Some days ago the well known Paris actress, Madame Dica Pelté, swallowed by accident some solution of corrosive sublimate. Medical aid was, of course, sent for, and while awaiting it the lady's mother wisely bethought herself to administer a cup of milk, and this antidote, there is every reason to believe, saved the daughter's life. Corrosive sublimate or bichloride of mercury is a salt to be found in every photographic studio, being commonly employed for intensifying negatives; it is a most violent poison, but the photographer has nearly always an efficient antidote ready in albumen or white of egg. If photographers would bear in mind the compounds, and their nature, formed under certain circumstances, they would, in most cases of poisoning, be ready to help themselves. Thus, if they will remember that mercury salts for the most part form with albumen an insoluble compound, as they do with the caseine contained in milk, it must necessarily occur to them that a patient poisoned by mercury would do well to swallow a substance which will combine with and render the mercury harmless. An emetic quickly administered is, perhaps, the best thing, first of all, and then the antidote should follow as quickly as possible. Again, take cyanide of potassium, which is also a most terrible poison. Most photographers know enough about chemistry to be aware that it forms with iron salts—the perchloride is best, but the ordinary proto-sulphate will do—the comparatively harmless compound, Prussian blue, and therefore the administration of iron is a good thing in cases of poisoning of this kind. Salts of silver, to give a third instance, may in the same way be counteracted by the administration of egg or milk (with which they form an insoluble compound), or of common salt, which, as every photographer knows, precipitates the salt as innocuous chloride. Antidotes for other mineral poisons are not more difficult to bear in mind, and it is the duty, therefore, of photographers to make themselves acquainted with them. We give these hints, not for the purpose of showing that a medical man is unnecessary in such cases, for his assistance should be invoked without a moment's delay, but with the view simply of showing how photographers may help themselves on an emergency.

NOTE ON THE SO-CALLED RETICULATION OF CARBON TISSUE.

BY H. BADEN PRITCHARD.*

THE phenomenon of reticulation must not be confounded with that of insolubility; the former is, to a certain extent, a curable defect, while the latter is not. A sheet of tissue which exhibits a uniform granulation of black particles over its surface on development may be regarded as having become, to a certain degree, insoluble previously to printing, and is valueless.

Putting on one side, for a moment, reticulation as it is found in practice, I would point out that the phenomenon is to be produced artificially in two ways:—

1. By maintaining the tissue at a warm temperature (say 100° Fah.) for a little while; fifteen minutes will suffice.

2. By placing the tissue under an air-pump for twenty-four hours, with plenty of sulphuric acid to absorb the moisture.

I have closely examined under a microscope, using a quarter-inch object glass, the phenomenon produced under these two conditions, and I append herewith drawings of it, as these two phases appear enlarged.

Heated Tissue.

Air-dried Tissue.

It will be observed that the markings are more exaggerated when the tissue has been heated than when it has been subjected to the more uniformly drying action of the air-pump. In the former case the reticulation has proceeded so far that I should term the defect incurable; but in the other instance, with caution, the tissue could be brought back to its normal condition.

When reticulation has proceeded as far as in the heated specimen I show, the appearance of the film under the microscope (after development, of course) is very similar indeed to the lifting of the film of a collodion negative, and, like the latter, the raised portions begin to crack and open when the film becomes thoroughly dry. In this case the lines run into one another like the cross markings on one's hands. I know of nothing that will mend matters under these circumstances.

Where, however, the reticulation has not proceeded so far, as in the case of No. 2 specimen, and the defect is confined to short lines or marks which do not run into one another, then the tissue may be made use of under certain circumstances.

Reticulation, then, in my opinion, is due to the gelatine in the tissue having been robbed of too much of its moisture, and having undergone a change from which it does not frequently recover, and then only with difficulty. It has suffered contraction to such an extent, that it is well nigh impossible to bring it back to its normal condition. The only way is to develop upon a basis that is not fixed. The single transfer process, by reason of the slippery character of the basis, permits the expansion again of the tissue, and this particular method favours, therefore, the recovery of the film to a great degree. It is the same with waxed plates (zinc, for instance), the coolness of the metal in this case also having a tendency to rehabilitate the gelatine; but a collodion film does not allow of the gelatine moving in this manner, and hence we find reticulation occurs most fre-

quently when collodion is employed as development basis, for the image will not stir from the firm grip it has taken upon the collodion. On some occasions I have found tissue useless for development on glass by reason of reticulation, which developed without a trace of that phenomenon on cold zinc plates well waxed.

Water as cold as possible should be employed in soaking the exposed tissue first of all, and an immersion for a few minutes will not do harm in hot weather; the development is then undertaken in water not too hot (the temperature varies much with the nature of the tissue and time of year), and a final rinse in hotter water still is sometimes beneficial in securing a clearer image and preventing any "swimming" of the picture from soluble pigment that may not have been washed away.

Too much stress cannot, in my opinion, be laid upon printing and preserving sensitized tissue in a cool locality.

NOTE ON CARBON PRINTING.

BY COL. H. STUART WORTLEY.*

HAVING now worked the Lambertype process for the past fourteen months, I am thoroughly satisfied with it. I had printed a good deal in carbon before, but never to my satisfaction. There are difficulties in it, of course, and my work being all of a large size I have had a fair share of them. The tissue itself is now very good, and any one who cannot work with it must blame only himself. The following few remarks may be of use:—I use the bichromate bath of various strengths, according to the density of my negatives, and always with the addition of ammonia. This addition has always been printed in M. Lambert's formulae, though lately erroneously credited to another gentleman by one writer.†

During last summer I invariably iced the bichromate bath, and met with no difficulty whatever on account of the temperature. I always pour a solution of wax over the plate, and never rub wax on the plate after the method of M. Lambert. Lastly, I mention that it will be found of great value to wash the collodion in tepid water in winter, as dipping it in cold water gives a tendency to break away.

LIGHT, EXPOSURE, AND DEVELOPMENT.

BY H. A. H. DANIEL.‡

AND now I will say a word or two on "how to expose." For views, I maintain that always, if practicable, a *long exposure and weak developer* give far the best results. I am of opinion that when a strong developer is used there is a much greater likelihood of hardness, and as a strong developer requires a quick exposure, I do think that such detail is given as with a long exposure. That is to say, in taking, for instance, the case of a landscape with fairly-lighted parts, and also very dark portions in the depths of the foliage, presuming a short exposure be given, and a strong developer used, I believe that the well-lighted parts assume a certain degree of hardness, and the dark portions of foliage do not contain so much detail. But suppose we use a weak developer, and give a long exposure, the details in the deep shadows get a longer time for impression on the film, and can be brought out slowly but surely by building up the negative; at the same time the weakness of the developer prevents any hardness in the well-lighted parts. But some may say, "If you give a short exposure, your developer is in accordance with it, and so the results should be equal." Theory may assert so, but I most decidedly affirm that theory in that case is false, and does not, as a matter of fact, harmonize with

* The addition of liquid ammonia to the solution of bichromate of potash was first suggested ten years ago in the work on Carbon Printing by the Editor of this Journal. In the early days of the process it was, we believe, often used by Mr. Swan.—Ed.

‡ Continued from page 27.

* Read before the Photographic Society of Great Britain.

practice and result. The picture on the table labelled No. 3 had seven minutes' exposure, and was developed with a weak developer, that is to say, about twenty grains, five grains more than I generally use, the subject being a remarkably dark one. In making exposures, there is one thing that should be continually studied: it is to endeavour to gain a tolerably accurate idea of the actinic power or value of different colours in nature, such as the light and dark greens, browns, greys, yellows, and reds. This can only be acquired by carefully noting the exposures, and examining, afterwards, the negatives, carrying the landscape in the eye as well as possible. By so doing a far better idea of the required length of exposure is obtained than by any other method I am acquainted with. We cannot rely on apparently equally lighted subjects, or recollecting the exposure of one subject and applying it to another. What appear to be equally lighted subjects are very often not so. By making this a little point of study, many a negative will be saved from under- or over-exposure. Again, if the subject be a very considerable distance from the tent, never should the wet blotting-paper of the back be omitted.

In a great number of cases a mistake is made as to the manner of uncapping the lens. We will suppose that the view comprises foreground, sky, and one of the sides of the picture in shadow. In uncapping the lens, the foreground and dark side should be exposed first, the sky being exposed last. If the dark side of the subject be on the right you would uncup the lens diagonally, beginning at the lower right hand corner, and coming gradually across obliquely, the effect being that the foreground and dark side would be the first to act on the sensitive plate, and so on later and later, till you came to the sky. The cap should be replaced in the same manner, only *vice versa*, beginning where you leave off. What often affords the greatest difficulty is to get well depicted a prettily clouded sky, and yet well expose the other parts of the picture. A most ingenious and useful piece of apparatus for effecting this object is a new kind of sky-shade, lately introduced, with finger-like projections which can be lengthened or shortened to follow approximately the outline of the sky, so that, prior to exposure, the sky can be shielded, and after half or more of the exposure has taken place, the shade removed, and the sky exposed. I have never used it, but have been told very fine cloud effects can be obtained in the negative by its help; but I have attained somewhat the same end by using the cap of the lens judiciously in a similar manner.

Relative to life in a picture, a little often adds greatly to the naturalness and reality of it, but I do not like to see it introduced as a sort of habit; but this is one more point which must remain with the operator's discrimination and good judgment. As to how to expose for portraits, I will just make a remark or two; but will not say much, as far more able pens than mine have written as to this, and I fear I have already tired you. One point that is very important is the position of the camera, which, if not carefully arranged, may ruin an otherwise good picture. If the camera be too high, so that it requires to be greatly depressed to embrace the subject, the effect is to give an entirely wrong impression of the pose, causing the head to appear as bent down, and showing far too much of the top of it. On the other hand, if the camera be so low as to be pointed upward to the sitter, the consequences are very disastrous, and far from flattering, producing the effect of a turned-up nose in an aquiline, and distorting the chin, and giving the impression that you are peering up underneath the chin, nose, and eyes, the effect being ludicrous and truly horrible. I think it will be proved that the best position for the camera is a little above the level of the sitter's eyes for three-quarter-length figures, and a shade lower for vignettes. There seems to be a rather prevailing opinion that portraits taken with direct sunlight effects are quite out of the question,

and not to be thought of. If more photographers would occasionally produce such, providing they be artistic, I think I can safely affirm that they would become to a certain extent popular. I have seen some most excellent pictures with such effects; one taken by a friend of mine in which the sitter, a gentleman, had a straw hat on. The sun was in such a position that it cast a sharp moderate shadow round the face, the straw hat entirely protecting the eyes from the sun's rays. There was full detail, and yet a most charming sunny day effect of an extremely pleasing character.

But of course the same thing may be done with good taste and judgment, and without any, in which latter case I can imagine a shocking effect. But they may be made with such a style of lighting very pleasing and attractive, without one atom of harshness, and I would recommend some of the members next season to try it. I would, while in this section, state my belief in what has been much discussed—viz., supplementary exposures to yellow light. I have found it more than once an assistance. No. 4 is an instance. That picture of a horse (a colour, by the way, not conducing to short exposure) was taken on a very dull, rainy, autumn day, with an exposure of a little over three seconds, which, of itself, could not possibly have been enough, but I placed it close to my tent window for three minutes, and the result was successful. Of course, the picture is not all that might be desired in all respects, but it is just what would be expected on such a day.

(To be Continued.)

THE BASIS OF PRINTING IN CARBON.*

A black mineral called chrome iron-ore occurs in nature, especially in Sweden and America. If this is fused with carbonate and nitrate of potash, a beautiful orange-red salt is formed, which is bichromate of potash. It consists, as implied by the name, of chromic acid and potash. Chromic acid and its salts are sensitive to light. Neither pure chromic acid nor chromate of potash are changed by light; they can be exposed for years to the sunlight without any decomposition being perceived; but as soon as a body is present that can unite with oxygen—as wood-fibre, paper, &c.—the light immediately produces its effect.

Gelatine is insoluble in cold water, but it absorbs cold water, and thereby swells. It dissolves in warm water, and if to this warm solution be added alum, or a salt of the oxide of chromium, or chrome alum, the gelatine becomes insoluble in water. Bichromate of potash and gelatine can be dissolved together in warm water in the dark, without the gelatine suffering any change from the chromate. If a sheet of paper be covered with such a solution of gelatine and bichromate of potash, and the film be allowed to dry, it becomes firm, and yet remains soluble in water as long as it is kept in the dark; but as soon as the film is exposed to the light the bichromate of potash is reduced to oxide of chromium, and this tans the film of gelatine; that is, makes it insoluble in water. Paper is coated with this preparation of gelatine and bichromate of potash coloured with a pigment, for example, lamp black; this paper is then exposed under a negative, the film is washed in hot water, which dissolves those parts of the gelatine unaffected by the light, whilst the insoluble parts retain their colouring matter, and thus form a picture.

The action of the light does not always penetrate the whole thickness of the film; the half-tones, therefore, have no support, and are destroyed in washing. Before immersing the films in hot water, it is necessary to transfer them to a sheet of paper, which is pressed in the dark on the coloured film of gelatine, and then the whole is plunged into hot water; the half-tones adhere to the paper pressed upon

* Extract from "The Chemistry of Light," by Dr. E. Voeltz (B. S. King & Co.).

an, and the image appears uninjured on it. The picture of course, reversed; therefore, if the reversed position is sired, the picture must be again transferred.

The moist gelatine film is placed, after exposure, upon a smooth zinc plate, to which, on drying, it becomes very firmly attached. The print thus attached to the zinc, immersed in warm water, the paper becomes detached, and the developed image adheres to the zinc plate. A sheet of white paper is now fastened upon the zinc plate and is allowed to dry. The gelatine picture adheres firmly to this paper, and may be detached from the zinc plate. The picture thus appears unreversed upon the paper.

SUGGESTIONS ON THE USE OF BACKGROUNDS.

BY L. W. SEAVY.*

BACKGROUNDS especially adapted for standing subjects seldom answer for sitting, for the reason that in exterior the horizon line is too high, and foreground not understood when seen without the middle distance and sky.

Six weeks ago I painted a background, expressly for use with a rail fence and bars, and in order that some of the distant landscape might be seen above the fence, I made the horizon high—represented a hill sloping towards the subject; farm houses embowered in the trees, &c.

After a week of trial, the photographer complained that there was nothing in the background; that it was too indifferent. On examination, I found that he was working it so far out of focus that it was scarcely seen on the plate, and that his trials, with but one or two exceptions, had been with sitting figures, and even those seated as low as possible.

It is safe to place a wall-painted background as near the subject as the head-rest will allow.

Quite recently a city patron complained that his ground was too light; that there was no strength in it; that the shadows were not near as strong as usual; and that he could not get sufficient detail to show the design. In his case he was working in a new light—very low top and side—and was using his material as per the below ground plan:—

Observe how much further out of focus the background is at A than at B. Then note that the light which enters the side-light is reflected to some degree (see dotted lines A X), and further consider the nearness of the background to the flood of light entering near X, which alone would take out considerable detail.

In what position, then, should the background be placed in order that it may affect the plate to its full value, the camera and subject remaining in the same position? The

* *Practical Photographer.*

following plan indicates the position which was suggested, and which effectually overcame the difficulties:—

It, therefore, follows that if you wish to make your background lighter than when worked at right angles to the side-light and to the camera, you should turn it toward the light, even at the expense of the detail. On the contrary, a slight turning from the light and from the camera will produce the opposite effect, still losing some detail.

Backgrounds with patterns, ornaments or straight lines, should not be used for heads or busts.

Don't use artificial or real rocks with balustrades.

Don't put base-boards on landscapes or interior backgrounds. They may be used with plain ones; still the mouldings are apt to take an objectionably high light.

Summer landscapes are hardly appropriate for ladies in furs, and gentlemen in heavy overcoats and fur caps.

In undertaking the use of set-pieces representing interiors, remember that consistency in lighting is necessary. The light should appear to come from windows and open doors, and not from the ceilings, as in a case lately under observation.

Many a theatrical set-scene is made effective and natural by the judicious use of lights.

Vertical lines should never intersect the figure in the centre of the head, or at its side, or the point of the shoulders.

Horizontal lines should never cross a figure at the neck, but should be below the shoulder, above or below the waist. Diagonal lines, such as falling shadows, or lines in architecture, should not intersect the figure at the point of the shoulder, elbow or waist.

In using backgrounds with indications of patterns on the walls, see that none of the lines seem to spring from the figure.

Elaborate backgrounds, carved furniture, curtains of heavy stuffs with rich borders, give an air of finish to the plainest photograph.

Study Chapman's American Drawing Book, Burnett's Composition, and read as much art and photographic literature as your time will permit and your means afford.

The illustrated papers and magazines will suggest many valuable ideas for composition, posing, and lighting.

Aim high, and maintain the dignity of your profession.

THE NEGATIVE BATH AND ITS TREATMENT

BY E. H. TRAIN, OF MONTANA.*

THE negative bath should be thirty-five or forty grains of silver to the ounce, and the more ounces the better. Small baths are too easily contaminated, and change rapidly. Having made your bath as large as your camera will admit, iodize it to two-thirds saturation, and let it to the sun twelve hours or more, or, if you cannot do the same thing, make it of water that has been cleared by adding a few grains of nitrate of silver plate, and if it fogs, add nitric acid, just —

it work clear, and then fool with it just as little as possible. Put nothing into it but good, clean plates; give it nothing but rest and work; never strengthen, neither add to nor take from it; skim it with blotting or filtering paper whenever there appears to be a scum on the surface, and filter only when it shows the need of it. A large bath thus treated should never fail to produce good results with any good collodion (for my formula, see in *Monies* for 1876), and the ordinary iron developer (say thirty grains of iron and an equal amount of acetic acid No. 8 to the ounce of water, and just enough alcohol to make it flow) until it has come to contain too much alcohol, or has become too small to cover your plate. This is my way to renovate and commence anew.

To renovate a bath, put it in an evaporating dish, and thoroughly neutralize with bicarbonate of soda, or what is much better, carbonate of silver made by throwing down some of your old bath with bicarbonate of soda, and washing the precipitate in four or five waters, and boil to one-third its original volume; let cool; filter; then add clear distilled water, enough to make the required volume; and lastly, strengthen to thirty-five or forty grains by adding adding crystallized nitrate of silver, and make slightly acid with nitric acid. This should work clear and nice. But if it should show any inclination of fog, add more acid until it works clear. If an old bath should not turn very black in boiling, be sure you have not neutralized it. If, for any reason, a bath should refuse to yield good results with the above treatment, the best remedy, I think, is fusing. To do this, evaporate to dryness in a sand bath (any old pan filled with sand to set your evaporating dish in will do), and heat until the smoking mass will ignite paper; then set your sand bath off the fire, and let it all cool together. Do not heat too hot, or you will have metallic silver.

Many of the brethren are troubled with a white deposit coming on the plate in hot weather. To avoid this, keep your chemicals cool, and let as little time as may be elapse between sensitizing and developing your plate; and if you still can not avoid it, it may be necessary to weaken your bath a little, but it ought not.

Another frequent annoyance in hot weather is a marbled appearance in the film, showing on the back side of the negative, and also showing in the print. This can be avoided by immersing the plate slowly—much slower than usual—but, of course, the motion must be steady and continuous to avoid streaks.

Now, a word about preparing plates, and I am through. Beat your albumen thoroughly; make it about twelve or fifteen parts water to one of albumen, and filter well. Immerse your plates for a few hours in dilute nitric acid; then wash well under the tap, and set in a bucket of water until ready to albumenize; then wash again; rinse with distilled water, and flow with albumen. Be sure your plates are kept wet from the time they leave the acid until they are flowed; wash well, and keep the dust off, and your plates will be clean and in good order for working.

Recent Patents.

THE PLATINUM PRINTING PROCESS.

The following is the text of Mr. Willis's specification describing the mode of printing in salts of platinum, for which he has obtained a patent:—

This invention has for its object improvements in the chemical treatment of the surfaces of paper, wood, and other suitable materials employed for receiving images from photographic negatives, or from any other object that may be inter-

posed between the light and such prepared paper or other surface. For this purpose, according to my invention, I apply to surfaces of paper, wood, and other suitable materials (by either one or more coatings) solutions or coatings of simple or compound salts of platinum, iridium, or gold, or a mixture of such salts. After this has dried, I sometimes apply another coating of a salt or salts of other metals. I then coat the material again, using a solution of ferric oxalate, or tartrate, or a combination of these salts with others, and again dry. I then expose the coated surface to light under a photographic negative, or other suitable object, till a faint brown image appears; after this I apply to the coated surface a solution of the neutral oxalate of potassium or other suitable oxalate, which speedily changes the brown tints to black ones. I then wash the surface thus treated for a short time in a dilute acid, and finally wash in water, but I sometimes immerse the surface in a solution of chloride of sodium, or hyposulphite of sodium, or other suitable salt, before giving it the final wash in water.

The following are several examples of the operations and manner in which I employ some of the chemicals above referred to in carrying my invention into practice:—

1st method. I coat paper with a solution of chloro-platinite of potassium containing ten grains of the salt to one ounce of water. After drying the paper, I coat it again with a solution of the nitrate of lead, forty grains of the salt to one ounce of water, and dry it again. I then coat it a third time with a solution composed of ferric oxalate, sixty grains to one ounce of water, with as little oxalic acid as is sufficient to render the ferric oxalate soluble. I then dry the paper, and expose it to light under a negative. On removing it from the negative, I float it, face downwards, on a hot solution of potassic oxalate. I then wash it in a weak solution of oxalic acid, then in plain water, and finish by immersing it in a solution of hyposulphite of soda, followed by a slight wash in plain water.

2nd method. In this method I proceed as in the first, but substitute an eight-grain solution of nitrate of silver for the nitrate of lead, and after removing the prints from the weak solution of oxalic acid, I finish them by an immersion in either a strong solution of chloride of sodium, or in a weak solution of that salt, followed by a weak solution of ammonia, supplemented in both cases by a slight wash in plain water.

3rd method. I coat paper with a solution of platinum bromide, twelve grains to one ounce of water, and dry. I then coat it with a strong solution of ferric tartrate, and dry. I next expose this paper to light under a negative, and afterwards float it, face downwards, on a hot solution of potassic oxalate. I then immerse it in a weak solution of oxalic acid, and finish by washing it in plain water.

I occasionally vary the preceding operations, or invert their order, or omit one or more of them. I would remark that I do not intend to confine myself to the use of aqueous solutions of the chemicals herein-before referred to, as the salts may be dissolved, and used with any suitable solvent. I sometimes mix two or more of the salts used for coating the paper or other surface before application.

Having thus fully described the nature of my improvements, and the manner of carrying the same into practice, what I claim for the production (on suitable surfaces) of photographic pictures in platinum, iridium, and other metals, is the application of solutions of potassic, ammoniac, or other suitable oxalate, to such surfaces after they have been exposed to light under a negative or other suitable object, and which surfaces have been coated previous to such insolation with ferric and with other salts, substantially in the manner herein-before described.

ANILINE COLOURS IN ART.—At a recent meeting of the Manchester Literary and Philosophical Society a letter was read from Mr. Joseph Siebotham, in which he calls attention to the fact of the growing use of the aniline colours for tinting photographs. He finds they are being extensively used in paintings and water-colour drawings, and the colours regularly sold for that purpose. Any one who knows the speedy alteration by light of nearly all of these colours will protest against their use, and a statement of this, with the authority of some of our chemists, would probably have the effect of causing them to be discontinued by all artists who care to think that their works should last more than a single year.—*Nature*.

HEALTH OF PHOTOGRAPHERS.

THE question often arises as to whether the practice of photography is *per se* an unhealthy pursuit. We have already stated a conviction that, pursued with legitimate precautions and ordinary prudence, it is not more unhealthy than a large number of industries involving close application, some strain on the nervous system, and possible contact with dangerous substances. It is less injurious than many chemical manufactures, grinding trades, electroplating, silvering looking-glasses, and others of the occupations recognized as tending to shorten life. It may, in fact, be pursued so as to be free from danger or injury to life or constitution. But as it undoubtedly involves conditions requiring the exercise of care and prudence, it is not out of course to raise a warning note now and then. The Paris Correspondent of our Philadelphia contemporary rates the dangers involved in the practice of the art somewhat seriously. He says in a recent letter:—

"I shall begin to-day by giving a cry of alarm to the profession, and declare that photography is a dangerous trade unless great precautions are taken.

"Photography being a new art, those who begun, if not ignorant of its dangers, were at least indifferent. But at present a cry of alarm must be raised; we have had to mourn the loss of too many who would have rendered great service to our art had they not been cut off in the prime of their lives. Many of the pioneers of photography have passed away too suddenly; the many deaths among the profession, the great number of operators who are suffering from a slow but sure disease brought on by their trade, make it a duty to inquire into the principal reasons for such a state of things, and call upon the profession to beware, and warn them at the same time of the precipice to which they are approaching ere it be too late.

"The business of the photographer presents many dangers, the more to be feared because they are invisible. The air of the dark room is too often contaminated with ether, alcohol, acids, bromine and iodine vapours, not to speak of the noxious vapours from the cyanide of potassium, which, mixing with the different gases and vapours, form dangerous combinations which poison slowly but surely the unhappy being exposed to their influence. The photographer lives in this poisoned atmosphere without its appearing to have any effect upon his health. I say appearing, but which declares itself after many months, sometimes after many years, by a stomach disease, too

happy if a chest disease does not complicate the damage already done.

"As I am a sufferer from want of former precautions, I advise all photographers—

"1st. Never to put any chemicals in the dark room that are not absolutely necessary.

"2nd. Never employ cyanide of potassium.

"3rd. Spare no expense to ventilate the dark room and the laboratory.

"4th. Never undertake to make nitrate of silver and other chemicals without being completely organized, and the laboratory separated from the other parts of the building.

"5th. Never drink spirituous liquors, for too much alcohol has been absorbed during the day's work.

"In following these simple rules, health and happiness will be secured.

The advice is so good generally, that without discussing the imminence of the dangers attending the practice of photography, we have no hesitation in endorsing it.

TONING WITHOUT GOLD.

FROM a communication from Messrs. Johnson and Matthey, which appears on another page, our readers will learn that a considerable reduction has been effected in the salts of palladium, to the use of which for toning purposes we referred in our last. This modification in the cost will probably render palladium salts more available for the purposes of the experimentalist, to whom, for toning purposes, it offers undoubted attractions where a tone of an absolute black, quite neutral, is required. As a toning agent for transparencies palladium possesses many advantages: toning with much delicacy and uniformity, without clogging or filling up the finest lines, or giving excessive density or thickness to the deposit of silver of which the image is formed. The pure black of the tone, and the delicacy of the image treated with salts of palladium, give the transparencies great value for lantern purposes. Some years ago we noticed some tones produced by the various noble metals other than gold, used either alone or in combination with gold, the results of a series of experiments undertaken by Captain Sellon, several of which we repeated with similar results. Many of the tones were very satisfactory indeed, but not superior to those obtained by gold; and we at the time came to the conclusion that no specific improvement was promised, unless economic advantages were involved, which at that time were not presented. The reduced cost to which the letter of Messrs. Johnson and Matthey refers, again brings the subject under consideration, and invites the attention of experimentalists. As a hint for those who may be inclined to try the palladium salts, we may remark that in the experiments of Captain Sellon, and in our own hands, they were treated in manner similar to the chloride or seleniochloride of gold. In toning transparencies and intensifying negatives a neutral solution, containing about six grains of the salt in an ounce of water, was found to answer well. Where a negative required a very slight degree of intensification after it was fixed, palladium possessed the special advantage of strengthening half-tones in due ratio to the dense parts of the picture. No apparent increase of thickness of deposit was noticeable, but the grey image of iron development acquired a black tone, which, being more adiastric, gave the negative greater printing value.

PHOTOGRAPHY IN HOLLAND.

WE subjoin a letter received from an old correspondent of the NEWS residing in Amsterdam, accompanying some excellent stereoscopic prints. Many of his remarks possess considerable general photographic interest. We print his letter as it stands:—

"DEAR SIR,—I have the pleasure to forward you by to-day's post a few photographs (as per list on another page). With the exception of No. 0, they are all from *dry* plates,

chiefly coffee-preservative. The Swiss views were all developed in the evening over a basin in the bedroom, and fixed when returned home. The stereograms are all taken with a binocular camera (Dallmeyer's lenses), and should you consider some of them worth mounting they are to be cut through the centre, and "right" to be placed left. The paper is —, which I consider among the best in the market; only when mounting the photographs they are to be thoroughly wetted, otherwise the paper cracks. As we have only very few amateurs here, and, until lately, no dry-plate workers at all (I, as president to our photographic society, try to stir our members up a little), I have no points of comparison, and am entirely self-taught, chiefly through the *News*, to which, and yourself, the photographic art owes so much. The enclosed photographs have all been fixed and washed as lately advised in the *Photographische Correspondenz*—i.e., they have been washed in three changes of water only, the two first containing *eau de Javelle* (solution of hypochlorite of soda). No. 0, the varnish whereof got spoiled, I made with Black's silver bath (five per cent. nitric acid, and no bromide in the collodion). You see, the exposure was nearly instantaneous, and the picture rather too soft, instead of hard, as might *a priori* have been expected.

"Last year I introduced here the carbon process, by translating the Autotype Manual. I do not think, however, that excepting two or three of the largest articles, it has come into general use. I think myself that there is still great room for improvement in that direction. According to my experience the actinometer is all wrong—i.e., in this sense: that one I had is frequently too much, and gives over-exposed pictures. Talking this matter over with one of our best photographers who practises the carbon process largely, he said: 'I agree with you, and have changed the Autotype actinometer, in this sense, that in lieu of the slit I made a circle, which I divided into four, each part having a different tint, but the darkest not higher in colour than the standard colour of the Autotype Company's actinometer.'

"On some glass transparencies made with 'the transparency paper' I got a liberal sprinkling of black grit (like coal dust), which my friend told me was the fault of the paper, or rather of the gelatine layer thereon. To amateurs these drawbacks are doubly disagreeable, as they render the process exceedingly costly. It seems to me that quite a different sort of negative is wanted; now we try to get them soft, and full of detail. For the carbon I think we require them full of detail, but very strong. I consider the reddish-violet colour of the transparency rather inartistic. Could the Company not imitate the colour of Ferrier's albumen glass transparencies?

"This morning I met in my album a portrait of mine made by the late Wothlytype Company in Regent Street, some twelve years ago, and printed with uranium. It is as fresh as on the first day, and, apart from all commercial considerations, it seems to be a very good process, after all. You will remember that the exact formula for working it was never given—in fact, Wothly told one thing in London and another in Paris. The Company now being defunct, do you believe Col. Stuart Wortley might be induced to give an accurate description of the process?

"This is rather a rambling letter. I hope it may reach you in good health and spirits.—Believe me, dear sir, very truly yours,

A. L. T. HAKMAN.

Amsterdam, January 7th.

RETAINING FULL GLOSS ON CARBON PRINTS.

ONE of the difficulties with the beginner in producing glazed carbon prints after the manner of M. Lambert is the loss of gloss in mounting, where the print has spontaneously left the glass before mounting. The manager of the carbon printing department in one of the largest portraiture establishments in Boston, U.S., sends us the fol-

lowing remedy for this trouble, and at the same time encloses some very fine examples of his work. He says:—

"Having, like others, perhaps, found some difficulty in obtaining at all times chromotypes with full glaze, owing to their leaving the glass before drying evenly, I have used lately, instead of a waxing solution, the following:—To one ounce of alcohol add five drops of nitric acid; rub the glass plate with a little on a piece of cotton-flannel till it feels smooth, and no lines or marks are seen; then with another flannel rub over with powdered talc; it will then feel slippery; run a line of dilute albumen round the edge, dust, and coat with collodion as usual. I find that the plate may be used two or three times with a rub with talc only after the first print has left the glass, but if it looks cloudy it is necessary to use the alcohol and acid again. This has also been used here for obtaining silver glacé.—Yours, "E. H. D."

EDINBURGH PHOTOGRAPHIC EXHIBITION.

(THIRD NOTICE.)

IT is unfortunate that, to make room for the Annual Exhibition of the Royal Scottish Academy, the Photographic Exhibition had to be closed on Wednesday last; but very gratifying, nevertheless, that, so far as we can learn, the whole of the exceptionally heavy expenses have been met, and a substantial balance left over. The council of the Edinburgh Photographic Society made a bold stroke, and their efforts have met with a suitable reward.

In portraiture the exhibition was very rich, but, with few exceptions, all were more or less retouched. It is, however, pleasing to be able to say that, on the whole, the work of the retoucher was well done. Mr. R. Slingsby, of Lincoln, exhibits some high-class work. His portrait of a lady (No. 418) has been a general favourite. Easy and graceful in pose, perfectly simple in composition, it forms a charming picture, which invariably commands attention. Messrs. Schulz and Suck, of Carlsruhe, send some very beautiful examples of portraits finished in crayon; No. 408 is, perhaps, one of the most satisfactory portraits in the galleries. Printed from a fine negative, to begin with, it has been wrought-up by a master hand in such a way as to retain the natural texture of the skin and the most delicate detail in the drapery. Dupont, of Brussels, shows a frame of six large portraits, specimens of most perfect silver printing and satisfactory posing. Numbers 4 and 5 are also examples of beautiful rendering of light gauzy drapery. Mr. A. Ford Smith, of Llandudno, has a number of fine pictures, principally combination effects, most of which we noticed while they were on exhibition in London. Peculiarly attractive in his "Reverie" (No. 569), in which, by a somewhat original pose, a really charming picture is produced. Mr. Marshall Wane, as usual, is well represented, and is well entitled to the award he has obtained; and the same may be said of Mr. J. M. Young, of Llandudno; his "Hide and Seek" (No. 457), for which a silver medal has been given, is one of the most pleasing portraits in the room, a single figure and a curtain being by very simple treatment made into a most charming composition.

Herr Kozmata, of Budapest, is also well represented. Especially noteworthy are two portraits of children (Nos. 407 and 411). The 18 by 15 plate is nearly filled by the pretty child in her night dress, and the couch on which she is so gracefully posed; and while holding in one hand a ball, and her chin resting on the other, she looks to the spectator with childlike confidence and simple wonder. The whole of Herr Kozmata's work, but especially the picture referred to, shows him to be master both in art and photography.

Of *genre* and combination photographs there is a large and good display. Mr. Robinson of Tunbridge Wells, Mr. Bruce of Dunse, Mr. Adam Diston of Leven, Mr. Johnston of Wick, Mr. A. Ford Smith of Llan-

dudno, and several other less known but meritorious workers, make a very creditable display. Pre-eminent in this line is Mr. Nesbitt of Bourne-mouth; his "Finishing Touch" (No. 208), and "Basting" (No. 215), are both excellent. The latter, in consequence of the simplicity of its treatment and perfection of composition, leaves little to be desired.

Mr. Bruce still sticks to the bluish colour that to many is disagreeable, and but for that his really clever pictures would meet with more general attention. Where all are so good it is difficult to particularise, but his "Dinner for me laugh" (No. 816) is, perhaps, the most attractive. The scene is thoroughly rustic, consisting of a kind of log house, an old tree, and a wheel-barrow. Seated on the latter is a happy-looking school-boy—as is indicated by books and slate—trying to play a flute; but the effort is in vain, as he is made to laugh in spite of himself by the actions of some of his school-fellows, who, however, are not in the picture. The subject as seen is in every respect very satisfactory, and equally so for what is suggested.

On another page will be found the report of the judges of apparatus, &c., and next week we hope to be able to give some definite information as to the actual results of the exhibition from a commercial point of view.

APPLICATIONS OF PHOTOGRAPHY TO THE CULTIVATION OF SCIENCE, ARTS, ETC., IN FRANCE, AS EXEMPLIFIED BY THE RECENT PARIS EXHIBITION.

BY M. A. DAVANNE.*

Touching the applications of photography to scientific research, M. Davanne says that the record of every astronomical phenomenon which is sufficiently luminous should find, as François Arago predicted, a powerful aid in photography. Astronomical observations are, however, of so delicate a nature that in applying photography to register them it is necessary, as a matter of course, to have special and very finely constructed apparatus for the purpose.

The greatest attempt that has been made to employ it in this connection was certainly on the occasion when many nations proceeded to observe the transit of Venus in December, 1874. Already, in 1860, MM. Laussedat et Girard had organised and accomplished, in the name of the *École Polytechnique*, an expedition to Africa, on the confines of the desert, to observe the eclipse of the sun on the 18th July, and had demonstrated the possibility of making photography serve the ends of the astronomer. The results of the work undertaken by the commission of the Academy of Sciences to observe the passage of Venus, and the different missions sent by that body to view the phenomenon in different parts of the globe, have proved anew the importance of the process. A numerous series of pictures was obtained, the greater part upon silver plates, and some upon glass. Thanks to the courtesy of the Academy, and especially M. Fizeau, our Exhibition has been in a position to show to the public some of these records, which remain as undeniable witnesses for the future of a phenomenon whose existence has hitherto rested upon difficult personal observations which it is impossible to check or control.

In choosing processes for the recording of scientific phenomena, M. Fizeau took care not to avail himself of substances which might be subject to alteration in shape or form. He refused to have recourse to films having material thickness, or such as might be changed on the application of developing or fixing agents. The rays of light acting upon the thickness of the film would give deformed images, or a wet film, when dry, might shrink, and thus render useless any calculations based upon mea-

surements of the image. M. Fizeau, in undertaking work of this character, stipulated that the pictures should be taken upon silver plates by the old Daguerreotype process, for in this case there was no fear of any defects arising from the thickness or deformity of the image. The work was rendered more simple, too, by reason of M. Fizeau having arranged matters in the case of every party of observers, and provided that the plates should all be fixed on return. Every transit of Venus party was entrusted with four hundred plates, and one may well judge of the care and pains taken by M. Fizeau in the matter by the success of the pictures that were taken by the several parties.

We may remark that M. Fizeau, completing the former work of Daguerre, changed the minutes necessary for the production of a Daguerreotype into seconds, in being the first to study the action of bromide upon Daguerreotype preparations, and to show, now thirty years ago, the photographic properties of bromide of silver.

For the expedition to Japan, M. Janssen constructed the special apparatus which he has termed the *revolver photographique*, and which being endowed with an automatic movement, permits one to record, within a given time, as many as forty-seven successive images. On account of the state of the atmosphere, it was not possible to verify, in the most absolute manner, the value of this little instrument to observe the passage of Venus, and whether the pictures obtained were as perfect as those secured with ordinary apparatus; but the *revolver* of M. Janssen must be considered henceforth as the most suitable instrument for securing successive images of a phenomenon which is itself subject to continual change.

A more favoured observer, one of the same party to Japan, was successful in securing at Kobe an image upon glass by means of wet collodion, and in this way it will be possible to determine the value of such productions from a mathematical point of view.

M. Janssen was also represented at the Exhibition by some large pictures of the sun, made direct, which showed all the spots and details upon the solar surface. These images were produced by means of a photographic lens, specially constructed of large size, which permitted him to secure plates in a very small fraction of a second.

The French Observatory was not represented, but the Observatory at Kew in England forwarded some specimens, which show to what extent photography may be made use of to record meteorological observations.

To record every instant the variations in the weight of the atmosphere, of the surrounding temperature, of the direction and intensity of the wind, the electricity, the terrestrial magnetism, the amount of moisture in the air, the condition of the sky, the intensity of the light and solar heat, &c., constitute an important total of considerable interest, especially when undertaken simultaneously in various localities over the globe. Such observations serve to permit observers to forecast the weather some days in advance, and to despatch important information to sea-ports and harbours, which is of vast service to the mariner.

To follow such observations day and night, every minute, is a task beyond human energy, and some of them are carried out by means of instruments of a very ingenious and delicate nature, in which electricity replaces the observer. But at Kew the simpler and more preferable plan is adopted of making a lamp write down upon a photographic surface all the movements of the barometer, thermometer, magnetometer, electrometer, &c. A series of curves, representing the variations of the different instruments, is traced upon iodised paper. The instrument work automatically for forty-eight hours, and the task the observer is in this way reduced to the operation of changing the sensitive paper every two days, and developing the traces written upon it.

(To be continued.)

AWARDS FOR INVENTIONS AT THE EDINBURGH EXHIBITION.

REPORT OF THE JUDGES ON APPARATUS.

SPECIAL judges were appointed by the Exhibition committee, to award at their discretion three silver and bronze medals for improved apparatus, materials, processes, &c. The following is their report:—

Your judges having carefully examined the various exhibits in these classes, are unanimous in granting the following awards:—

1. A Silver Medal to Professor Charles Piazzi Smyth for 1031, the plano-concave corrector. This is a new optical arrangement which, being placed in close proximity to the prepared plate, completely prevents the effect of the spherical aberration of the portrait or other lens, and allows full aperture to be used. In the example exhibited this is adapted to a brass camera, which has several extremely ingenious arrangements for obtaining copies of objects in rapid motion.

2. A Silver Medal to Mr. H. Fox Talbot for 1135, three specimens of photo-glyphic engraving. These prints, although produced from negatives which are by no means perfect, are examples of the earliest process of photo-engraving on metal plates, and exhibit in parts a perfection which is not surpassed by the most beautiful of the many fine examples of modern work of the same class. This invention dates from 1853, when the process was first published.

3. A Bronze Medal to Mr. L. Warnerke for 1134, being his ingenious adaptation of sensitized collodion tissue for the production of transparencies, negatives, &c. Although not the invention of the exhibitor, still the adaptations have been carried out so skilfully and completely, and the entire arrangements made so simple, that he may be said to have made into a workable process that which was not so before.

4. A Bronze Medal to Mr. P. Meagher for 1138, an improved folding camera for single pictures 9 by 7 and under. This camera, without being too complicated in design, contains many improvements and adaptations, some of which are new and highly ingenious, and the workmanship is excellent.

5. A Bronze Medal to Mr. Wm. Birrell, of Hamilton, for his automatic oxyhydrogen apparatus. Repeated trials of the apparatus show that it gives a steady, constant light, and is capable of great extension in power.

6. Your judges, while confining themselves to these five awards, may remark that several of the exhibits merit favourable mention, among which are those of Messrs. Geo. Mason and Co., Kemp and Co., Mawson and Swan, George Hare, &c.; and had they not been precluded by the stringent rule laid down that objects, materials, and processes in competition must be exhibited by the inventor or maker thereof, they would have had pleasure in considering many of them, and also Willis' ingenious platinotype process, specimens of which are exhibited, but not by the inventor.

In cameras for changing dry plates in the field they would have made an award, but that of Jonte, of Paris, is not exhibited by himself; and that of Aird, in addition to being in the same category, could not be adjudicated upon in consequence of Mr. Aird being one of the judges.

DAVID AIRD.

IMPROVEMENT IN THE PRODUCTION OF LICHTDRUCK PRINTING PLATES.

BY J. HUSNIK.*

THE recent suggestion to employ mixtures of soluble silica with albumen should afford considerable advantages to the Lichtdruck process, and simplify it considerably

* *Photographische Correspondenz.*

The plates made with this admixture of silica last a very long time, and are, indeed, almost indestructible. Moreover, their preparation may be conducted at any time—by daylight or candlelight—and a large provision of them may be made at one time without any fear being entertained in respect to their deterioration. I have had to modify my former formula in one respect only, and that is in regard to the quantity of water added; for I now employ less water. In this way the mixture is produced of a less fluid character, and the plates at the upper end, when previously they began to dry, now appear sufficiently prepared, which was not formerly the case, as the gelatine at this margin, for an inch or an inch and a half, did not adhere sufficiently well.

To prepare the plates, I take—

White of egg	7 parts
Water glass or soluble silica	...	5	"
Distilled water	...	5	"

If dried albumen is employed, then only one part, and not seven, is taken, and the amount of water is raised to six parts. If, however, my earlier preparation is preferred, then I would recommend that the plates should be coated twice and permitted to drain at opposite corners; but all this I hold now to be superfluous. The further treatment of the plates is the same as I have before described.

In respect to the manner of pouring on the gelatine, I have, however, made some material alterations. It is impossible sometimes to avoid little cavities during the drying of the gelatine plate. These spots always appear on the print as black spots, and the purity of little pictures especially is thereby spoilt. These defects are due to the bursting of very small and almost invisible bubbles during drying. The parts cannot close up any more, while the gelatine, from drying, has become too thick to blend together, and the consequence is that there remains a minute puncture, which takes ink when the roller comes over it. I have noticed that this defect occurs with all operators. It may be avoided, it is true, when boiling water is employed for rendering the gelatine fluid, and when, moreover, the solution is maintained for a long time in a hot state. All the air-bubbles come to the top (and the incipient skin contracts), so that the spreading of the fluid gelatine upon the plate has to be done very carefully. A large quantity of solution is poured on the plate, and allowed to spread out slowly (paper strips being used to aid it), and then the solution is poured off, and some fresh applied, of which only as much is made use of as remains behind when the plate has been quickly reversed. Manipulating in this manner secures clean results, but it is only after considerable practice in the work that even films are secured, and that one gets to know how much solution is required for plates of a certain size.

A much more certain method consists in adding a good deal of spirits of wine to the gelatine solution, and permitting the plate to remain in a slanting position at an angle of about 10° in the drying box. Only, in this case, it is necessary after drying the plate to pour over it the same solution a second time, and, upon letting the surface dry again, to reverse the position which it previously occupied. The drying should be conducted at a temperature of 45° C., and the plate must be brought to this temperature previously to the gelatine solution being applied. The manipulation of the plate must be conducted as rapidly as possible; the drying box must be quickly opened and the plate taken out; the gelatine solution must be applied without delay, the superfluous liquid poured off, and the plate put back again into the drying box before it has had time to cool. Under these circumstances the film is dry in half an hour. The same precautions as regards rapidity must be taken in the case of pouring over the gelatine a second time. In this way, it is true, only two plates can be dried at one time, because the opening of the box too

frequently would otherwise lower the temperature; but, in any case, it must be remembered that in an hour two plates are prepared, and, therefore, in a few hours a goodly number of them may be prepared.

In the double coating of the plates with gelatine solution another important obstacle is got over, which, however, is inherent to the drying box and to the nature of the plates. As is generally known, the plate must be placed in a horizontal position with great care, by means of screws, which fit into iron lars. This is, however, not so easy to do as it appears to be. In the first place, no plate of glass is perfectly level or flat, and this defect is especially noticeable in large plates; secondly, not a particle of dust must be allowed to get under the spirit-level if the trial is to be a trustworthy one; and, thirdly, the iron bars themselves are apt to expand as the temperature increases, so that the plates resting thereon alter their position, and although the films may have been put in the box in the first place perfectly level, the temperature alone suffices to rob them of their horizontal position. Finally, the wood of the box will often shrink or warp (one can hear it crack audibly sometimes during the process of drying), and this again alters the horizontal position of the plate. And if the plate has not remained quite horizontal during drying, the gelatine is found to be of a thicker nature at one side than the other; the result is that the picture, when struck off is darker on that side where there is least gelatine, and lighter where there is most of it to be found. Large plates I have never found to be perfectly uniform, and in those of average size one is able to see some sort of difference, so that only the middle of the plate is sometimes to be used for printing small pictures. By having recourse to a double coating of the plate, the matter is far more favourable to success, and I believe that the disciples of *Lichtdruck* will be well served when this improvement gets widely known.

Gelatine solution containing much spirits of wine flows over the plate like collodion, and does not contain any bubbles; moreover, on the superfluous liquid being drained off, it leaves a mirror-like surface, which it is altogether impossible to produce without the employment of alcohol.

The solution, I may mention, is prepared in the following manner:—Six parts of fine gelatine are put into forty-eight parts of cold water (it need not be distilled water) to swell, and then warmed in a water bath, and finally brought to a boiling temperature; at this point one part of bichromate of ammonia is added, and then forty-eight parts of ordinary methylated spirits of wine are added. The mixture is now stirred so that all the bubbles rise to the top, and the solution is filtered through filter paper or a rag. The solution is made use of while in a warm condition. It is well to keep the solution, if it is to be used further, in a warm condition, and enclosed in a stoppered bottle to prevent evaporation of the spirit, the bottle being put away in the drying-box to maintain it at a sufficiently high temperature for use.

The pictures from these plates have a very fine grain, like ordinary photographs, and are particularly clean. A good printing-plate must appear grained all over excepting in the very high lights. The grain permits the water, on moistening the gelatine, to penetrate, and in this way the printing proceeds in a most uniform manner. Plates that appear to have too little grain in the shadows produce prints that are caked in the dark parts, and do not absorb water. They yield, usually enough, on the third or fourth application of the roller, images of a flat and bald character. In this case they must be washed with turpentine in order that more water may be allowed to permeate into the shadows of the plate.

Such plates as these are not, however, useless. The beautiful grain is more easy to secure the higher the temperature of the drying box, and the more chrome salt is used, and the more roomy the drying apparatus. One must not, however, exceed certain limits in the matter. If

too much chrome salt is employed, it is apt to crystallise out; and if, again, the temperature employed in drying is too high, the salt will decompose the other substances at hand.

As regards the colouring matter to be employed in printing in admixture to lamp-black, I may mention that madder appears to be the only pigment that can be thoroughly recommended for such purpose. All other descriptions of carmin and lacs are to be regarded with suspicion, and should be made use of only under exceptional circumstances. Madder, unfortunately, is a costly pigment; and not only that—it is often obtained in commerce adulterated or spurious, and for this reason I have for some time past cast about for another colouring matter as permanent and cheaper. This I have found in dark iron-violet. There is also a light iron-violet to be purchased, which has, however, too little body and power, and for this reason I always prefer to employ the former. It is very rich and economical when rubbed down with lamp-black, and imparts to the pictures a magnificent purple-violet tone. Moreover, it does not colour the gelatine on the plate, as is the case with carmine and various gums; and it is unaffected by light and external influences.

PROPOSALS FOR UTILISING THE WASTE PRODUCTS IN CARBON PRINTING.

BY DR. J. SCHNAUSE.*

Those who occupy themselves continually with the carbon and *Lichtdruck* processes must frequently regret that they have to pour away such large quantities of useful materials with their washings. Some experiments which I have made for the purpose of ascertaining how far these waste products may be utilised again, are not as yet complete, but they have taught me, at any rate, the lesson that where one has to do with large quantities of the material it is a paying matter to collect such residues, any outlay being fully recouped by the results. Time and trouble, too, are so insignificant in the matter as hardly to enter into consideration.

As an instance, I may mention the saving of the chromic acid from the washing of *Lichtdruck* plates. In the preparation of these I employ, almost exclusively, bichromate of ammonia, and as this is much more expensive than the bichromate of potash (the former costs 14-00 marks per kilo., or seven shillings a-pound, and the latter 1-30 to 2-60 marks per kilo., or eightpence to sixteenpence a-pound), I tried to get back the ammonia salt from the washings, after precipitation of the gelatine present by the aid of tannin, by evaporating the liquid, having previously taken care to employ but a little clean water in the first washing. A portion (if very little) of the bichromate I knew would be robbed of its chromic acid by exposure to light, but yet, by this mode of proceeding, I obtained a mass which was very impure indeed, by reason of the amount of organic matter mixed with it. A more profitable plan is, therefore, to take the first washing, which can always be treated with a little acetic acid to decompose the bicarbonate of lime, and to precipitate the chromic acid as chromate of lead by the addition of a sufficient quantity of sugar of lead solution.

In the case of a concentrated chromate solution, the chromate of lead is precipitated of a more beautiful and intense colour (especially if spring water is used to which acetic acid has been added, to prevent the formation of the white carbonate of lead) than when a dilute chromate solution is operated upon. The price of acetate of lead is one mark per kilo., or sixpence a-pound, while that of chromate of lead is five times as high.

If the development water from pigment or carbon printing is collected in a large vessel, the colouring matter (chromate of lead) gradually sinks to the bottom. *—after*

* *Photographisches Archiv.*

fine state of division, which is certainly useful for many purposes.

Perhaps these few lines may induce some of my colleagues to consider the matter, and to undertake some experiments towards promoting economy in this branch of photography.

JOTTINGS FROM MY NOTE-BOOK.

BY T. FODRAKE.

Babies' Portraits.—Never pose a baby, or even a child three years old, until the plate is ready, the size of the figure decided on, and the focus as near as possible obtained. Then watch your opportunity; as soon as the plate is in the camera, the child will watch your movements, and as soon as the expression is right, slip off the cover, give it two or three rapid turns with your hand to arrest the attention of the child, and the thing is done. The leather cover is far better for this work than the instantaneous shutter. But for babies a month, six weeks, or two months old the thing is different; they really take no notice, but mothers will have them photographed, and that, too, with their eyes open. Turn their faces from the light, get a third party in the room to move rapidly a newspaper about four feet from the direction they are turned, and you arrest the attention long enough to catch the likeness. Never try more than two or three times, if you fail, either with children or babies; you only exhaust your patience and chemicals to no purpose; let them come again. Never try babies without a quick lens and good light; if you do, you will fail, and your customers will give you no credit for trying, but only remember your failure. Adopt the above hints, and you will rarely fail in getting satisfactory results, and putting money in your pocket; for if you photograph the children right, you will get the adults.

A Warning.—A photographer may accidentally produce "fulminate of silver," and by that means engender serious consequences to himself and others. If a nitrate of silver bath be warmed, and alcohol be added, a white precipitate is deposited, which is the compound referred to, and is highly explosive. If a photographer should evaporate a silver bath that has long been in use, and is both acid and contains a large amount of alcohol, he must be very careful to avoid an explosion.

Test Papers.—Test papers should be carefully protected from the atmosphere, otherwise they assume a purple hue through the action of carbonic acid, which is present in infinitesimal quantities in the air. If they are then immersed in a half pint of water containing about two drops of liquor potassa, they are restored to their former colour.

Correspondence.

AMATEUR VARNISH MAKING.

DEAR SIR,—In the *News* of the 19th inst., in reply to correspondents, to "R. D. F." you say: "We do not counsel amateur varnish making, because the selection of resins and solvents, and their proper mixture, require much experience, and failure is often a serious matter." Will you allow me to suggest that if your correspondent wishes to prepare his own varnish he can do so cheaply and well, and without any difficulty or risk of failure. Let him buy at any oil shop one pint of white hard spirit varnish, and dilute it with one pint of methylated spirit, and filter, and he will have a capital varnish which is very hard. One drop of castor oil to each ounce of the varnish gives it a good bite for the pencil. For the above I am indebted to Mr. Sydney Smyth in the *Year-Book* for 1875. I have used it in my business ever since, and find it answer well. Thinking it may be useful to your correspondents, I have reproduced it.—Yours truly, T. S. SWARTZMAN.

CHLORIDE OF PALLADIUM FOR TONING PURPOSES.

DEAR SIR,—Referring to a notice upon the use of the salts of palladium for toning in lieu of gold, which appeared in your last issue, it may interest your readers to know that the principal photographic chemical dealers are now supplying the soluble chloride of palladium at a lower price than the salts of gold, which it will doubtless supersede to a great extent.

The salts of rhodium and iridium, though more costly, also give most interesting results, and have, like those of palladium, been employed for some time past, to a limited extent, for first class work.—We are, dear sir, yours faithfully,

JOHNSON, MATTHEY, AND CO.

Hatton Garden, London, January 22nd.

CARBON TRANSPARENCIES.

DEAR SIR,—I perceive in your last edition of the *News* a communication from Mr. J. R. Sawyer, to Dr. Vogel, of the method employed by the Autotype Company in the production of carbon transparencies, in which he recommends coating the tissue with collodion, previous to attaching it to final support, as described by me on page 261 of last volume. I have sometimes used an ordinary albumenized plate as permanent support, after coagulating with hot water, then coating the exposed tissue with very thin normal collodion, bringing in contact under water, and pressing firmly together with squeegee, with excellent results. But the most simple of all methods for producing carbon transparencies for enlarging is as communicated by me to this year's *PHOTO. NEWS ALMANACK*. I have enclosed a few specimens for you, Mr. Editor, to express your opinion upon.—I remain yours truly, FRANK DORE.

[The examples enclosed are excellent.—Ed.]

"PICKING UP" THE CARBON PROCESS.

SIR,—I beg you will give me leave to endorse the remarks in your last issue, under the above heading, as to the unseemly tone of "A Successful Worker," whose condemnation of acquiring information, or picking up hints, through the journals, if carried out consistently, would render your journal, sir, quite needless, except as an advertising medium.

Take my own case as an instance, and I doubt not hundreds are similarly placed. I keep no operator, preferring to meet personally my customers. My time, when not occupied with sitters, or copying, is devoted to the books, or superintending the reception room, and looking after my three men, viz., artist, mounter, and printer. The latter prints well in silver, but quite fails in carbon. Now I cannot afford to devote my whole time for even three or four weeks to this, in order to teach him. A gentleman did call round and demonstrated before him (for a fee), but it was pretty well a failure, owing, he said, to his tissue, brought with him, being too old. I therefore ask, in common with "A Carbon Experimentalist," for the most convenient appliances money will buy, in order to facilitate as much as possible the working of the process. Can we get a proper boiler, with Bunsen burner, rose, dishes, &c.; in fact, all the apparatus required in working the process commercially?

I am afraid of your scissors, or the waste basket, or I would have written further on the subject. At present I sign myself, sir, your obedient servant,

ANOTHER ANXIOUS TO LEARN.

Talk in the Studio.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At the next meeting of this Society, on Thursday next, February 1st, in the Rooms of the Society of Arts, Adelphi, Mr. William Brooks will read a paper on "The Emulsion Process applied to Transparencies, and Enlarging, &c., without a Nitrate Bath."

TRANSPARENCIES ON GLASS.—We have been favoured by Mr. Wm. Brooks with some transparencies on glass, in which the tone is exceedingly rich and fine, produced by development without any subsequent toning. The colour by transmitted light is a deep warm brown or smoke colour. They are printed on plates prepared with bromide emulsion, and developed with alkaline solutions, the best tones being produced by Mr. Brooks' modifications of the alkaline developer. Mr. Brooks will read a paper on the subject at the next meeting of the South London Society, and enter into full details. He observes that the production of stereo transparencies on glass seems to have died out, probably because the cost of production renders them too expensive for the market; but as the method he employs will materially cheapen production, he hopes it may aid in reviving this branch of the art, especially as thousands of stereo negatives are now lying idle which might be productively employed. The subject well deserves attention.

PRINTERS' ART UNION.—We notice that the show cards announcing the sixth annual drawing for prizes in connection with the above give photographs, executed by the London Stereoscopic Company, of two oil paintings forming the second prize, the subjects being "The Willing Slaves," by P. Jackson, and "Fou-y-gross" (or the Head of the Cross), by Eleanor Brown, S.F.A.

M. ED. BACQUEVELL.—*Nature* notes that this gentleman, to whose researches photography is so much indebted, has been elected president of the French Physical Society, which seems, like its English sister society, to be doing excellent work.

CENTENNIAL ITEMS.—Mr. J. T. Dexter, the representative of the *Paper and Printing Trades Journal* at the Centennial Exhibition, writing under the above heading, says:—"Of chromos and photographs there is virtually no end. Photography, in the skilled hands of R. Newell and Son, is the father of the best of many artistic memorials; producing pictures of large dimensions of the unoccupied site, the buildings during erection, and the grand aggregate of structures in which the Exhibition was embraced. With such views as these before one, the eye taken in the whole area—extensive as many a London parish—and all that it contains, presented with unerring fidelity, and so as to give clearer notions than it is possible to obtain from any number of separate illustrations. When it is said that the work is worthy of the occasion, the fittest tribute is rendered to Messrs. Newell's skill, identified already as that was with the 'Old Landmarks and Relics of Philadelphia.'"

"THE AUBELTYPE PROCESS," says *The Paper and Printing Trades Journal* ("invented by Aubel, of Cologne), by which can be obtained good typographic reproductions of engravings, consists in preparing a photographic negative on glass with a salt of silver, and depositing more silver in the battery. The silvered plate is subjected to the fumes of hydrofluoric acid, which eats away the parts unprotected by metal, and so prepares the matrix of the plate."

To Correspondents.

SILVER THREAD.—The formula (as you will see) is quoted from an American contemporary. The cotton seed would, doubtless, be one of the samples made and sold in America, where, as American photographers in many cases make their own collodion, good commercial samples are in the market. In this country, good pyroxyline is not so easily obtainable. To use the formula you must make or buy the best sample you can, and use it in such proportion as will give a collodion of a satisfactory consistency. Of a good sample of cotton four or five grains to each ounce of solvents will generally give a collodion of a satisfactory consistency for ordinary work. In our own experiments in the manufacture of collodion we have generally found it desirable to make our own soluble cotton, using the formula we have published in the *News* and in several of our *Year-Books*.

H. W.—No iron developer should stain the negative if properly used. Stains on a negative are more often the result of imperfect manipulation than of any fault in the developer. If the solution does not flow evenly, stains will, of course, be produced, but this may be remedied by skill and care in applying the solution, or sometimes the addition of alcohol may be necessary. The addition of a little sugar is also a remedy at times.

ENQUIRER.—We cannot tell you with certainty the cause of the spots without knowing more of the processes through which the print has passed. They suggest that the print has been toned in a turbid solution. If chloride of lime, for instance, were employed in the toning bath, and portions of this had settled on the face of the print, such a result would be produced.

JOHN ENNIS.—If the name be written upon the negative with any non-actinic pigment (reversing the letters, of course, that they may appear in proper order when printed), they will, of course, appear all right in white letters on the print. Indian red, or cadmium yellow, answers well for the purpose; after mixing a portion to the proper consistency on a palette, a fine sable pencil may be used in writing. A good carte lens may be used for enlarging purposes, and is more convenient than a larger lens of long focus. The *Year-Book* for 1875 may be obtained at our office.

AGENCY NOTES.—Success in photography as a profession depends chiefly upon photographic skill and business ability. How far you would be likely to succeed we cannot, of course, offer any opinion, beyond remarking that the amount of capital you possess, although small, might, with the requisites we have named, be sufficient. The training you name in a chemist's shop generally induces habits of neatness and precision which are valuable in photography. The scale of advertising charges of the *Photographic News* generally appears in some part of the advertising pages, and may always be obtained of our publishers. You will find details in the present issue.

R. T. W.—The process of producing prints in Prussian blue is one of the oldest of photographic processes, and all details regarding it have been repeatedly published. In the work on photography published by Mr. Robert Hunt in 1851 the history of the process and all details are given. In our last issue, on p. 34, you will find details. In the second solution there named the water should be 2 ounces, and the ammonia citrate of iron 140 grains. The process is not difficult, and the materials are not so expensive as in silver printing.

H. WARREN.—We have published many methods of printing photographs upon wood. Much depends upon the purpose intended as to which is the most suitable process. The permanent ink photograph which appears in our *Year-Book* is produced by a photo-collodionic process, in which the print is obtained in a printer's ink in a printing press, worked on the same principle as lithography. We have published full details of several such processes in the *News* and in our *Year-Books*. You will find information on the subject in the *Year-Book* just issued, and in the issues for the last few years. We regret that we cannot answer questions on photographic subjects by letter.

LANDSCAPE PHOTOGRAPHER.—You may still register your views, and may then proceed against any one who copies them after registration. But a difficulty here arises: you will find it difficult to prove that the copy was not made from one of the early prints issued before registration. It is not necessary to register different sizes of the same picture. We make it a point to publish all the information available upon the photo-collodionic processes. The chief thing necessary for success in their practice is experience, which can only be obtained by personal effort.

CANVAS.—There are various processes for printing on painter's canvas, which we have published. One of the best modes of obtaining photographs on canvas consists in transferring a collodion transparency or a carbon print to the canvas; or the surface may be treated with a chloride, and sensitized with silver. In this case the surface of the canvas should first be well cleaned with alcohol, and the chloride applied in a weak solution of gelatine. The solutions may be applied with a brush, or the edges of the canvas may be turned up to form a dish, and the solutions flowed over the surface. The latter is the best mode of applying the developing solution, which should consist of a 4-grain solution of gallic acid.

E. D. BIRD asks how to "get photographic spots out of photographic prints after they are fixed." We do not quite understand what he means by "photographic spots." If he means silver stains, a little solution of cyanide of potassium, applied with a camel's hair pencil, will probably serve.

H. W. D.—We do not remember the address of M. Jones, nor has he, so far as we know, any agent in England. Herr Warnke, who took some interest in explaining the working of the camera, can probably give you the information. His address is 10, Linden Grove, Peckham Rye.

B. RICHMOND.—Thanks. As a rule, however, communications in verse are not suitable for our columns.

PRODUCING BLUE PRINTS.—In the article on p. 34 of our last number on this subject there is an error. In the "second solution" the proportions of water and ammonia-citrate of iron require transposition, making water two ounces, and ammonia-citrate one hundred and forty grains.

W. KURTZ.—Thanks in advance; prints have not, however, arrived yet.

H. TAYLOR.—Thanks.
Several Correspondents in our next.

The Photographic News, February 2, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

HONOURS TO SCIENTIFIC PHOTOGRAPHERS IN FRANCE—NON-SUCCESS OF THE TRANSIT OF VENUS PHOTOGRAPHS—A SPECIAL CORRESPONDENT IN SCIENTIFIC CIRCLES.

Honours to Scientific Photographers in France.—The scientific men of France are doing honour to their photographic investigators just now. The *Academie des Sciences* has elected M. Peligot, the president of the French Photographic Society, to be president of the *Academie*, and M. Fizeau, whose name is well known as an early worker at Daguerreotype, has been nominated vice-president. M. Peligot succeeded M. Balard in the *fauteuil* at the French Photographic Society, and has presided over its meetings and deliberations since the death of the discoverer of bromine. M. Fizeau's name is known to most photographers as one who worked earnestly to convert the Daguerreotype image into a printing block. He was one of the first to perceive that in order to perfect a process of light-printing, something should be done towards producing a cliché or block from which further examples could be produced. Daguerreotype, though presenting a most beautiful and delicate result, could not be multiplied in any way. For every image that is desired a fresh exposure is necessary, and this inconvenience M. Fizeau set himself to overcome. It was his object to convert the Daguerreotype image into a block from which impressions could be pulled in ink. Before, however, the French investigator had gone very far, Fox Talbot had convinced experimentalists that his method of producing images upon a transparent medium was, after all, the most promising; and so it proved, for the English photographer soon distanced every other competitor in the field. For Talbot's paper photographs, which could be printed through, and thus made to serve for the production of copies equal to the original, were at once so simple of preparation, and so perfect in their nature, that M. Fizeau saw there was little to be gained just then by pursuing his investigations, and therefore abandoned them. Lastly, however, since mechanical printing has made such rapid strides, M. Fizeau's process has again been talked of, and we doubt not that further experiments will be made in the matter to ascertain whether or not some practical phototype or photo-engraving process cannot be elaborated to vie with those brought forward now-a-days. M. Fizeau did a great deal towards developing a mechanical process from the Daguerreotype plate, and if but a practical plan could be elaborated, it would offer many advantages. The silver plate that receives the image being of a solid unyielding nature, the image is invariably sharper and more true than that secured upon a spongy collodion film, and hence, for scientific purposes especially, the Daguerreotype process will always retain a place among photographic processes.

Non-success of the Transit of Venus Photographs.—While on the subject of scientific photographs, we may mention that rumours come from Paris of the unsatisfactory character of some of the photographs taken during the Transit of Venus. These pictures, as most of our readers know, were secured in order that measurements might be taken from them, and for this reason, seeing the minute nature of the images, it is absolutely necessary that they should be free from all suspicion of distortion. Unfortunately, this does not appear to be the case, and we are told that out of a thousand plates which have been examined under the microscope in order that they may be measured; only forty-seven have given satisfaction. Unforeseen difficulties are said to have arisen, and altogether the affair is not progressing favourably. Such intelligence as this is most deeply to be regretted after the expense and labour involved in securing the images. The French savans, it may be remembered, extended their journeys to Japan to secure their results, and

besides the many thousands of pounds expended by the French Government in fitting out and transporting the expeditions, there are the devotion and labours of the gentlemen who took part in the investigations to be considered. In respect to the work of our countrymen, but very little has transpired, outside the walls of the Royal Observatory, beyond the first news that the measurements were progressing favourably. We trust we shall not be deemed impatient if we express a hope that some intelligence may soon reach us of the results which the Transit of Venus observations have yielded, for it is now just two years that the records were secured. It was said that Russia, by reason of the skill and practice of its mathematicians, would be the first to present us with the results of the international observations; but as yet not a sign has been made by any of the savans engaged in the calculations.

A Special Correspondent in Scientific Circles.—It is seldom that the general public take much interest in scientific proceedings, at any rate to such an extent as to employ special reporters, as they did, for instance, in the case of the Transit of Venus just alluded to. The reason of this is, doubtless, the fact that scientific phenomena are rarely put forward in a manner to be popularly appreciated. One great point in the success of Faraday as a lecturer was, doubtless, the circumstance that he had a happy manner of expressing a dry scientific fact in interesting and homely language. As a rule, however, science is presented in too abstruse a form to be generally appreciated; and a phenomenon must be a popular one indeed to secure a good place in the newspapers. Nevertheless, opportunities do occur when special reports on scientific matters are eagerly looked forward to, and when early news is so desirable as to call for the services of that energetic being—the special correspondent. With such men as these, nothing seems impossible; and as instances of their invasions into the domain of science are rare, we may be permitted to cite a case which came under Mr. James Glaisher's notice some years ago. As everybody knows, the Royal Observatory at Greenwich is sacred ground; visitors, it is true, are permitted at certain times, and under certain restrictions, to view some of the rooms and laboratories about the place; but, for the most part, the establishment is kept hermetically sealed, so far as the public are concerned, whose profane footsteps are not allowed to tread the hallowed chambers. A solemn silence reigns throughout this temple of science, only broken by the tick of clockwork and the regular beat of pendulums. The assistants quietly record their observations and make their calculations; such work needing little interchange of words or conversation. On the occasion of which we speak, the staff happened to be unusually busy, for an unprecedented shower of meteors had been predicted, and to record the number of these was the arduous task of all concerned. The shower had been spoken of in the newspapers in every part of the globe, and thus a public, as well as scientific, interest attached to the phenomenon. At midnight the fiery shower began, and the heavens were for hours studiously watched by expert sentinels. It was a clear, still night, every star shining forth from the skies, and silently and rapidly the Astronomer-Royal and his assistants pursued their work. The small hours of the morning still found them at their labours, and four o'clock struck before the last of the stars had fallen from heaven. "That makes 7521 up to four o'clock precisely," said one of the assistants, half aloud. "I beg your pardon: how many did you say?" returned a voice unexpectedly from behind him. The assistant turned and found a stranger, and a total stranger. How the latter came to be there no one knew; so suddenly had he appeared that he might have fallen from the skies, only he did not look like a star. "7521," repeated the assistant, all amazement; "but who are you—where did you come from?" The stranger carefully noted the information, and then said, very quietly, "Thank you, thank you very much indeed! I am a special correspondent on the *New York Herald*." How the stranger got there, how he had

to act upon the image for some time, I let the liquid run off, and when necessary pour over fresh cyanide solution, and finally rinse thoroughly with water. Should the image after this treatment remain still too opaque and dense, the experiment must be undertaken a second time, only care must be taken to allow the film to dry before processing.

The action of the solution upon a dried film in this way seems to be more energetic than where the silver image is free of all impregnation with water.

As the film may receive a tendency to leave the glass plate, especially if the pressure is repeated more than once, it is well, before beginning the experiment, to coat the margin of the plate with varnish, so that the liquid may not loosen the edges. I may call attention to the circumstance that the tone of a plate treated in this way is altered in a very palpable manner; it assumes a yellowish tinge, which, as every practical man knows, yields far better prints than plates possessing a bluish tone.

TRICKS AND TRUTHS.*

[A CONVERSATION BETWEEN DOCTOR AND ARTIST.]

SCENE.—Operating Room at Hastings, White and Fisher's Gallery.

Artist. Now, Doctor, how would you like to appear in this photograph?

Doctor. Well, make it as you think a doctor should look in a picture.

Artist. But there are a variety of expressions: shall it be the one you would assume on being called up at midnight, or that at the recovery of your patient?

Doctor. I should prefer that smile of satisfaction one would be likely to exhibit on receiving the amount of a bill he had considered lost.

Artist. You have some experience in that line, doubtless. Now, I like doctors. If I were not an artist, I would rather be a doctor than a governor!

Doctor. I think the profession of doctor is the most useful of the two.

Artist. Of the three, you mean. Now, see here, a doctor is more useful than a governor, and an artist is more useful than a doctor!

Doctor. I should like to know how you make that out. Don't you think that will be difficult to prove?

Artist. Difficult? Oh, no; governors would die without doctors, and doctors only make men fit for the artist; and then you know the works of doctors die in the bodies of men, and by artists' works the bodies of men live for ever. Now sit down, please.

Doctor. Quite an argument, indeed. You have been very successful in business here, I am told.

Artist. Quite so; our business has assumed greater proportions than we anticipated in the outset. We started without a specimen, and it was uphill work for awhile. Ah, Doctor! specimens are in demand even in the medical profession.

Doctor. Good ones, you mean, of course? But is not the reputation of your photographs due somewhat to the fact that they so often flatter the originals?

Artist. Very likely; of course we take out the wrinkles, if there are any, as the camera makes them appear harder than in the original. Then we straighten the nose, if it needs it, and smooth away the harsh lines. Once in awhile we run across a party who orders them to be left in, but this is seldom the case.

Doctor. Are your customers, as a general thing, exacting and hard to please?

Artist. Some of them are. Look this way, please. As a matter of course, they all want to be made good-looking. For instance, about a year ago a lady desired a photograph

of herself to look as near like Mrs. Scott Siddons as possible. She was very fleshy, and just the opposite of what she wanted the camera to make her in the picture. Here was a case where we must be untrue to nature, or lose the trade. We made the picture. It was unlike Siddons in everything but position. We then sliced the arms down to proper size, took the superfluous flesh off the face, tapered down the waist, and rounded off the form to order, and the lady was perfectly charmed with the result. Now turn the head so.

Doctor. But this must have been an isolated case.

Artist. Not at all. We can accomplish a great deal by means of photography, and the resources of our art are still unfathomed. Not long since, a young man died suddenly, who had never had a sitting for a picture of any kind. His family were very anxious to get some kind of a portrait. We went to the house, and succeeded in getting a good negative of the features and general expression of the dead man (the friends said the corpse looked very natural); of course the eyes were wanting. We eliminated everything deathly in the negative, put in the eyes, and finished it in crayon, and when the family looked upon the finished portrait, they pronounced it perfect in every particular. Are you tired, Doctor?

Doctor. Oh! no. I was going to ask if men are as hard to please as women?

Artist. Yes, and sometimes more so. Some of the men who engage sittings are quite fussy about the shape, position, and general appearance, and often desire a second or third sitting, because some piece of wardrobe was not properly adjusted to their taste.

Doctor. How do you manage to get along with such people?

Artist. That is quite a trade in itself. We agree to give them sittings until they are suited; but some of them never are; but as we require a deposit when the negative is made, it has a tendency to shut off those who sit just to see how they look. There now, all ready; wink as much as you please. [Plate exposed.]

Doctor. I was thinking during the exposure why it happens that while the photograph is true to nature in regard to form, that the white seems too light and the dark too dark. How do you explain this?

Artist. While I am developing this plate I will place in your hands Dr. Vogel's opinion on that subject, as he is the highest known authority.

[Artist disappears and Doctor reads.]

"Critically speaking, the photograph does not represent the exact order of light and shade one finds in nature. Light objects require a short exposure, dark ones longer, and as both must be taken together, it is not always easy for the operator to get a good picture. He must select a tasteful position, and secure a good expression of the face; but this expression is ever varying from a thousand circumstances, so that the photographer is not necessarily to blame."

[Artist returns.]

Doctor. I should judge from this that harmony should exist between complexion and costume in order to secure the most favourable results.

Artist. That's just it, Doctor. True, we can control the light much better than we did a few years ago; but where the face is very white the dress should not be very dark. We have such cases very often, and, of course, as the one or the other must be sacrificed to a certain extent, it is usually the dress, as the face is considered the feature in a picture. If people would study this in regard to sittings, they would secure more pleasing pictures.

Doctor. And the business of furnishing people with copies of their loveliness, you say, is increasing?

Artist. Increasing every year. There is absolutely no limit to progress in the art, so that a year hence everybody may want a new picture.

Doctor. You say the proofs will be ready to-morrow. Well, I will send a boy in for them.

Artist. Excuse me, Doctor, but a proof is an unfinished picture, and fades quickly; and although many of our patrons have taken the proofs to show their friends, yet we have always felt that it was not just to them or to ourselves, for in many instances we have known the proofs to fade before the party most interested had seen them; besides, it does not correctly represent the picture as it will appear when finished, and must consequently misrepresent our work. To avoid this, our customers come now to the gallery to inspect their proofs.

Doctor. All right; no one can blame a workman for guarding his work until it is finished. Good day.

[Exit Doctor.]

AN OLD BATH.

BY E. F. GREENE.*

CAN the negative bath be over-iodized? has been one of the subjects of discussion before our Society for the last two or three meetings. The general opinion among photographers has been that what has been called a "pinhole" bath is an over-iodized bath. Mr. Hall's able paper on this subject at our last meeting† illustrated to us that it is not iodide of silver which causes pinholes. Iodide of silver, in excess of the amount dissolved in the solution, will precipitate to the bottom, or can be filtered out; but no amount of filtering will cure a "pinhole" bath.

If it is not iodide of silver, what is it; and can it be avoided? We are all aware of the trouble it has caused us, and if it can be avoided, it will confer a great boon upon the photographer. I will state that I am using the same negative bath I used fifteen years ago. Of course, it has had copious additions to it in the shape of nitrate of silver and water; and I can assure you it has been full of pinholes a great many times, and has had all the ills the bath is heir to; also it has been dosed and doctored by all the known remedies, but for the last five or six years I have adopted but one practice, as follows:—Pour the solution into an evaporating dish, and put in enough of bicarbonate of soda solution to make it slightly alkaline, and evaporate enough by heat to drive off the alcohol and ether; when cool, add water to bring it to forty grains to the ounce; then sun it for ten or twelve hours; let it stand until it is settled perfectly clear; filter, and it is ready for use.

It will require a few drops of nitric acid; but do not add the acid until after it has been filtered, as the acid will dissolve the dirt and foul matter, which will filter out when neutral. I have not taken any other method to get rid of what is called excess of iodide in the bath for the last five years; and I do not believe it is necessary to precipitate the iodide of silver in the bath. I have not discovered but what I can dip as many plates in the bath by this process of purifying as I used to when I practiced the old method of precipitating iodide of silver by adding water to the bath.

In the minutes of the meeting as published in the *Western Photographic News* for June, I am reported to have said that I used washed iodide of silver to iodize the bath; it should have been credited to Mr. Hall. I dissolve iodide of potassium in water, and add directly to the bath. The quantity the bath will take up is so very small, there is no use in going to the trouble to prepare washed iodide of silver. One grain of iodide of potassium will saturate thirty-two ounces of forty-grain bath; that quantity cannot injure it when a bath which has been in constant use for years, and has had thousands of plates dipped into it, remains in good working order now, and is better than a new one.

The members then discussed the subject at some length. Question by a member: How many plates can be immersed in a bath before pinholes appear? Mr. Greene said he had dipped one hundred 5 by 8 plates in a 7 by 9 bath. Mr. Smith said he used three-quarters of a grain of iodide to

one grain of silver. Mr. Greene used a bath saturated, or added iodide as long as it would dissolve, until there was a sediment at the bottom. Mr. Drummond had used gelatine to get rid of the water in the collodion, still there would be pinholes. He had put three or four ounces of water in a bottle, poured his silver bath into the same, filtered, used, and found the pinholes had all disappeared.

VIOLET GLASS FOR STUDIOS.

REFERRING to the statements of M. Sottellari regarding the use of violet glass, Mr. Gaffield, of Boston, U.S., writing to our Philadelphia contemporary, says:—

"I have only to say that such a claim is in entire contradiction of all my experiments for the last nine years with colourless glasses of many kinds and glasses of all colours. My experiments have all been made with paper sensitized with chloride of silver. The poorest kind of colourless glass, and even those kinds which have been changed to a yellowish or purple tinge by exposure of years to sunlight, will transmit a much larger amount of the chemical rays than the most actinic of the really coloured glasses, the blue and violet.

"I have never made any experiments with iodide or bromide of silver, and I shall not have time with my present occupations to make any before the publication of your next number. I have no idea that any different results will be attained, and I have not seen any photographer in Boston who 'takes any stock' in the so-called 'invention,' which is said to be patented in France.

"I would like to add, that in a series of photo-metrical experiments, made by Professor Frederic E. Stimpson and myself in 1867, we found purple or violet glass to cut off about 90 per cent. of the light rays. I have never yet expressed in mathematical terms the amount of chemical influence cut off by coloured glass, but I should think that violet glass would transmit from 25 to 30 per cent. less than any colourless glass.

"Under the circumstances, it is difficult to conceive of the remarkable effects named under violet glass. As Professor Stebbing says, 'The fact is, an error is committed by him, or that iodide and bromide salts are more sensible to violet rays than chloride of silver, with which the experiments of Mr. Gaffield were made.' I think it would be well for some competent person to seek the truth, for it interests the whole photographic community."

"I do not pretend to be the 'competent person' suggested by my friend, Prof. Stebbing, but for my own gratification, and as soon as I find opportunity, I hope to make a few experiments on iodide and bromide of silver under colourless and coloured glasses, and will communicate the results to you."

PRODUCING A LARGE PHOTOGRAPH.—At a meeting of the Philadelphia Photographic Society, at the request of one of the members, Mr. Clemmons gave an interesting account of the manner in which he successfully albumenized a single sheet of paper measuring 10 feet 7 inches by 20 inches, which was afterwards used for a mammoth print of the Centennial Grounds from George's Hill. A wooden dish was constructed, 11½ feet long by 27½ inches wide; this was first painted white inside, then coated with shellac, and finally waxed, pure bees-wax being well rubbed into the seams by means of a large piece of cork. The salted albumen was now poured in, covering the bottom to the depth of about ¼ of an inch all over, and it required the whites of 125 dozen eggs. The paper, after being soaked, was carefully lifted off by two persons, and secured to a long pole by its upper edge, galvanized iron tacks being used for this purpose. Seven different negatives, each 18 by 22 inches, were used in the printing, the edge of each being blended with care into that of its fellow. For making the negatives, the back combination of a 21-inch Ross symmetrical lens, 42 inches focus, was found to be the only lens at hand giving the required field and definition. Photographed by J. Gutkunst, Esq.

THE COFFEE PROCESS AGAIN.

THE coffee dry process seems more than ever a favourite, especially with amateurs abroad. Colonel Baratti, it will be remembered, was one of the early workers with this process; while many other distinguished amateurs on the Continent, with the late M. de Constant at their head, seem never to tire of singing its praises. A correspondent in Switzerland lately sent us some examples of the process which, by reason of their depth, vigour, and richness, were equal to the best wet-plate photographs, and now both M. Haakman, the president of the Photographic Society at Amsterdam, and M. Victor Angerer, a well-known Viennese photographer, bear testimony to the efficacy of the process.

M. Haakman says he has given some attention to dry plates, for, as he practises photography simply for pleasure, these are generally more convenient to use than wet films. He has tried, he tells us, tannin, tea, tobacco, morphine, and several other substances in the preparation of his dry films; but none of these, to his thinking, afford such clean and satisfactory films as coffee.

M. Haakman prepares his plates in the simplest manner; and although we have several times published formulæ in regard to the production of coffee plates, our readers may like to know the precise plan followed by M. Haakman. His coffee solution is made up of

Boiling water	...	100 cub. cents.
Pure Java coffee (burnt)	...	5 grammes
White sugar, dissolved in a little water	...	2½ "

This infusion, when cold, is poured twice over the sensitized collodion films, which are then dried.

FADED LICHTDRUCK PRINTS.

SOME discussion arose a little while ago upon the stability of pigment or carbon photographs, and it was proved beyond dispute that some of the colours employed in the production of these pictures were liable to fade or bleach. An objection of the same kind has been lodged against Lichtdruck prints, and a case is mentioned in the *Mittheilungen* which certainly brings home the charge of instability in the case of a certain batch of such prints. Photographers who have taken up collotype printing have become callous, we suppose, in respect to the ink and pigments that they employ, and, in their endeavour to secure delicate and fine gradations, make use of colours whose charms are fleeting.

In a recent number of his journal, Dr. Vogel tells us

that, the other day, comparing some Lichtdruck prints, preserved in his portfolio, with pictures of the same kind which had been in a photographer's show case for some time, he was astounded to see the marked change these latter had undergone from the continued action of daylight. They had, first of all, lost the warm brown tone they originally possessed, and then gradually changed to a grey, the high lights becoming even yellow.

It is, of course, easy to avoid the use of fleeting colours, and photographers must do so if they wish the public to believe in the inalterability of their productions; unfortunately many of the cheaper and more delicate pigments to be purchased in commerce are very liable to bleach in sunlight.

FASHIONS IN PHOTOGRAPHY.

MR. FITZGIBBON, in his *Practical Photographer*, thinks that the journals have hitherto been negligent in failing to apprise the profession of the prevailing fashions in size and fitting of photographic portraits, and gives the following as the styles at present fashionable in America:—

CARD MOUNTS.

The most generally used is thick or heavy round corners, light buff, dark buff, green, grey, white, or rose tint.

A finer quality of cards are light buff, dark buff, white and amber, with broad, red borders.

Another first-class card mount is white, cream, opal, silver grey, rose tint, violet, primrose, green, fawn, steel grey or drab.

The most fashionable colors of enamelled are chocolate, white with gilt and tinted lines, pearl, pink, buff, green, rose tint, and primrose.

The finest quality, and fashionable, is the cream, pink, pearl, buff or green, with gilt lines. Also, white, primrose, green, pearl, pink, black or chocolate, with broad gilt and red borders.

The tinted backs, fine quality, are becoming very popular

THE CABINET

most used has round corners with figured and tinted backs; white, pearl, pink green, and primrose enamelled backs and unenamelled faces, with broad gilt borders. The finest used, and most popular at present, are black or chocolate colour, enamelled on both sides, with broad gilt borders.

The colours most in demand for a cheaper card mount are amber, green, pink and violet, with gilt lines; also black, maroon, or dark green enamelled backs, and unenamelled amber coloured face.

Slee's mounts of all sizes hold their popularity, and there is about fifty per cent. of the same used. The most popular and desirable colours are white, light and dark buff, amber, pink, rose, green, and violet. The most expensive are the fawn, drab, or steel grey. The lines on those mounts are purple or red. Victoria size, very few are used.

THE PROMENADE

generally are square corners. The finest and most fashionable are the pink, pearl, and chocolate, gilt edges. The next are amber, white, light buff, with red edges bevelled.

SOMETHING NEW.

The imperial and boudoir cards. The most fashionable colours are white, amber, pearl, tea, granite, blue, or grey with round corners.

THE CATHERSON

Ferro holder is something new also. They are very neat and attractive, and are of different tints.

STEREOSCOPE MOUNTS

range in popular colours like the card mounts. Three and a-half by seven is still the popular size, although a good many of the others are sold.

MATS OF ALL SIZES.

Most popular colour is white. Grey is also a favourite tint. Black and chocolate are coming into fashion.

HINTS TO AMATEUR CHEMISTS.

THE following advice to young chemists, given by Mr. W. W. Goodwin in a work on Analysis just published in America, is so applicable to the case of photographers, that we commend it heartily to all our younger readers:—

"Cleanliness is of the utmost importance. Never put away anything dirty. It takes twice the time to cleanse glass vessels when chemicals have dried on them than it does if washed directly after they are done with. Many persons have thrown away bits of dirty apparatus which they would have looked upon with pride had they polished them before putting them away. Do everything and arrange everything in order. Never be in a hurry or flurried; serious accidents may occur at times through not keeping cool. Have a place for everything, and put everything in its place. It is a good plan to make a list of all apparatus and materials required for the experiments which are to engage the attention. Satisfy yourself beforehand why you do everything, and never be content with making a thing merely do, if it is not done properly. Badly fitting corks, requiring lutes or sealing-wax to stop the leaks, must not be suffered at any time; another should be fitted. Many a serious explosion has occurred for want of these precautions. In all cases use the simplest form of apparatus for an experiment; unnecessary complications are confusing.

Take careful notes of experiments as they proceed, on paper or in a rough note-book. Dr. Hofman used to say, "The scrap of paper well stained with acids is of much greater value than the half worked-out though clean notes written after the experiment has passed away." The rough notes should be reproduced in a more finished form in a book kept solely for that purpose. The mere copying of scientific facts and formulae, previously learned in a practical way, is a great help toward remembering them.

Chemical operations should be carried on, if possible, in a room set apart for that purpose; it is better to have it on the ground floor, if possible, as water is more easily obtained, and waste carried off by drains. It should be well ventilated, with a flue in which there is a fire burning, or furnished with a ring of gas jets, to produce an ascending current. The flue may be furnished with a hood, under which experiments may be performed where noxious vapours arise. A zinc tube about two and a half inches in diameter, arranged over the bench, about a foot from the ceiling, with inverted funnel tubes over the gas-lights leading into it, can be arranged to produce an upward current, and will keep the room clear. This may be carried into the flue or out of doors. A chamber about two by one and one-half feet, with glass doors, should be fitted up in every laboratory, however humble, in connection with the flue, in which the experiments with sulphuretted hydrogen, &c., can be carried on. This, however, can be made to lead out of doors also, by having a Bunsen constantly burning, the waste heat being used for a mand bath, in which evaporations may be carried on, if the chamber be divided by a partition. The principal sink may be either in the laboratory or just outside, and should be of glazed stoneware, to resist acids. A small leaden or japanned iron basin may be let into the bench to carry off waste.

The room should be furnished with a working bench (say) two and one-half feet broad, round the wall, and, if necessary, down the centre. A nozzle, with a stop-cock, should be connected with the gas-pipe for attaching the flexible tube; narrow shelves should be fixed along the walls and over the bench, to hold the bottles containing materials and reagents. A cupboard or shelves may be put under the bench, and drawers fitted, to hold the various kinds of apparatus. Water must be at hand in a trough that can be emptied, or in pails.

FRENCH CORRESPONDENCE.

M. BOIVIN ON CARBON PRINTING: THE DIFFERENCE BETWEEN WEAK AND STRONG LIGHT—A NEW AND FACILE ENLARGING PROCESS—M. BOISSONNAS' STUDIES OF CHILDREN—FORMIC ACID DEVELOPER MODIFIED.

I THINK that the readers of the PHOTOGRAPHIC NEWS will not be averse to reading a note which I have just received from M. Boivin regarding the difference of sensitiveness existing between bichromated mixture and chloride of silver paper employed usually in the photometers. All photographers occupied in carbon printing must have remarked that the sensitiveness of the tissue they employ is very variable, according as the intensity of the light varies and the amount of bichromate salt contained in the material. The chloride of silver paper is, however, far more open to influences, and sometimes a photographic action will be remarked (after a certain exposure) in the tissue, while the chloride of silver has apparently undergone no change at all.

A very important point results from this observation; it is, that in a bright light it is necessary to prolong the exposure to a high number on the photometric scale, and in a weak light the exposure should cease at a low number. For instance, a cliché marked No. 3 on the photometric scale, and giving a good print in fifteen minutes' time, must be printed scarcely up to No. 3 degree, if as much as thirty or forty minutes are required to furnish an impression. If, on the contrary, the light is brighter than usual, and only eight to ten minutes are necessary to yield a print, then the exposure must be continued till No. 3 degree appears very pronounced on the scale. The chemical action is produced much more slowly upon chloride of silver paper by a weak light than a strong one, while in the case of the bichromated tissue, it is not the same under similar conditions, and under some circumstances, therefore, it is possible to produce carbon prints when silver impressions cannot be obtained. According to M. Boivin, it is this variation in the sensitive qualities of the two bodies which must of all things be borne in mind in producing good carbon prints, and it is by giving attention to this circumstance that he has been enabled to produce fine impressions with certainty. If photographers would only bear the fact that he has pointed out in mind, they would at once surmount one of the gravest difficulties connected with carbon printing.

An amateur, Doctor L. d'Hombres, a medical man residing in one of our little provincial towns, writes to me that he has discovered and employs a process of enlargement which necessitates no retouching at all, and gives at the same time the most beautiful results, which hitherto have been secured only by considerable aid from an artist. By means of his system, he assures me, there is no necessity for any particular arrangement or apparatus; the paraphernalia he makes use of is of the simplest, and he does not even possess the accomplishment of sketching. He produces, he tells me, prints of every dimension and the most perfect delicacy. The outlines are perfectly sharp, and they may be produced with the ease and rapidity involved in the preparation of carte portraits. If this is a true record of his invention, Dr. d'Hombres has certainly made a vast step of progress; but I can only speak by hearsay at present, and so far have seen no results produced by the new method.

A photographer of Geneva, M. Boissonnas, who has already distinguished himself at various photographic exhibitions, paid me a visit in Paris during the past few days, and took the opportunity of showing me some really wonderful pictures. They were portraits of children produced instantaneously; nevertheless, they presented all the vigour and modelling which are to be seen in photographs that have been fully and thoroughly exposed. Some were of babies crying, and some of little ones laughing; some there were in the act of lifting arms and legs,

and all of them were full of movement and life. Groups there were of children represented in the middle of a game, with a cat or dog in their midst. If not actually instantaneous pictures, they must have been secured with the shortest of exposures, so animated were the pictures. The four albums which M. Boissonnas exhibited to me included something like 800 prints of this kind; so that one may very well believe that the photographs represent a fair specimen of that gentleman's every day work.

In one of my former letters to the PHOTOGRAPHIC NEWS (Vol. XX, No. 951, page 561) I gave your readers the formula of a developing solution made up with formic acid, which permits of the exposure being materially shortened. The solution is composed of:

Sulphate of iron...	40 grammes
Sulphate of magnesia ...	40 "
Formic acid ...	5 "
Alcohol ...	30 cub. cents.
Acetic acid ...	10 "
Water ...	500 "

The author of this communication tells me that he has slightly modified this formula with the purpose of rendering it more manageable. For every 100 cubic centimetres of water he adds five grammes of glycerine, while the acetic acid has been reduced to four per cent. The formic acid should not be added until just before the solution is used. On development, the image appears rapidly, and then appears to sink into the film, if regarded by reflected light. Looked at as a transparency, however, all the details are perfectly visible. It is necessary to intensify by means of pyrogallie acid and silver. The collodion recommended for the preparation of plates is composed thus:

No. 1.—Ether ...	500 parts
Alcohol ...	400 "
Pyroxyline ...	10 "
No. 2.—Absolute alcohol ...	100 "
Iodide of cadmium ...	6 "
Iodide of ammonium ...	6 "
Iodide of lithium ...	1 "
Bromide of cadmium ...	1.25 "
Bromide of ammonium ...	1.25 "

The two solutions are mixed in the proportion of ninety per cent. of No. 1, and ten per cent. of No. 2.

ERNEST LACAN.

APPLICATIONS OF PHOTOGRAPHY TO THE CULTIVATION OF SCIENCE, ARTS, ETC., IN FRANCE, AS EXEMPLIFIED BY THE RECENT PARIS EXHIBITION.

BY M. A. DAVANNE.*

AFTER dealing with the applications of photography to scientific research, M. Davanne proceeds to show the value of the art in paleographic and numismatic studies, as also in respect to its worth in libraries, where it may be employed in copying rare historical documents. In support of this last important application of photography, M. Davanne quotes a letter from M. Leopold Delisle, the Director of the National Library of France, who says:—

"Photography should lead to a complete revolution of paleographic studies; henceforth the most important manuscripts may be reproduced with the most rigorous exactness from the first page to the last, and a day will arrive when all the large libraries in the world will have copies of those few antique volumes which are the glory of the museums at Rome, Florence, Milan, Vienna, Paris, and London. The Psalter of the University of Utrecht has just been the object of publication at very little expense at the British Museum, and thus students have put within their reach, and may with confidence study, one of the most curious monuments of caligraphy and draughtmanship of the eighth and ninth century."

* Continued from page 44.

Another example of how photography helps the student interested in these matters is to be found in the reproduction of a Popish Bull of Sylvester II., which is dated 3rd November, 999, and which carries the signature of Pope Gerbert. This instrument, once reproduced upon stone or metal, can be vulgarized to any extent, and thus documents are reproduced for a few pence which may be perused with as much confidence and advantage as the originals, that are so rare and valuable as to be jealously stored up from the eyes of all but a very few.

M. Davanne proceeds then to say something of carbon printing, and refers to the works of M. Braun more especially, some of which were shown at the Exhibition. The pictures of M. Braun, says M. Davanne, without being very numerous, possessed, nevertheless, more interest than those he has previously forwarded. Among his beautiful prints were to be seen reproductions of the paintings of Michael Angelo, in the Sistine Chapel, the merit of which reproductions is only to be appreciated when one takes into consideration the many difficulties that had to be overcome. As most successful in portraits produced in permanent pigments, M. Liebert and M. Beutlinger are cited, two Paris photographers who have already won a reputation for themselves in other branches of the art.

Turning to photo-enamels, M. Davanne says that the transformation of a cliché into a vitrified enamel is one of the most delicate applications of photography, demanding, in order to be successful, a very great degree of skill, not only in regard to the manipulations connected with the muffle furnace, but also in respect to the development of the image with fusible pigment, in which operation the hygrometric condition of the atmosphere plays a very important part. This branch of photography is most suitable for portraits, apparently; in some of the enamels exhibited in Paris the brown tone which is usually adopted was replaced by tints of various shades, which proved that the photographer had been exceedingly skilful in his retouching labours. The process is destined to be very generally developed, and when it has been well cultivated we may hope for enamels at a much more moderate price.

Photography in greasy ink naturally calls for M. Davanne's earnest attention, and he states that a transformation of a photographic cliché taken from nature into a printing block from which any number of impressions can be struck off in greasy ink is one of the most important problems which photographers of the future will have to solve. The perfect realization of this problem in all its ramifications will constitute an immense stride of progress which will at once modify all our graphic arts; and it is with this aim in view that many have striven far on the way to success. So far, the mechanical processes might be divided into three classes, impressions being struck off a gelatine surface as in lithography, or produced from intaglio or relief blocks.

M. Davanne concludes his report with a glance at the improvements made in photographic apparatus as exemplified by the instruments exhibited at the recent Paris Exhibition.

ON THE CLEARNESS OF THE ATMOSPHERE—A QUERY.

BY NELSON K. CHERRILL.

PHOTOGRAPHERS in England, and, perhaps, elsewhere, are accustomed to hear remarks from their clients, which point to a wide-spread belief that clearness of the atmosphere is an essential condition to the success of photography. Englishmen who have travelled are, as a rule, rather inclined to be "down" on the home photographers. Who does not remember hearing often enough the photographs of Italy or Belgium compared with English work, to the detriment of the latter; and the reason set down as final and conclusive that the wonderfully clear atmosphere in these countries is the sole and simple cause of the superiority of the photo-

graphs produced in them? I do not suppose for a moment that an exceptionally clear atmosphere would make any perceptible difference in the quality of a portrait taken in the studio; indeed, so far to the contrary, some of the finest portraits I know of have been taken in weather quite the reverse of clear. How far clearness of the atmosphere in its extreme qualities of perfection would affect a landscape photograph, I have no means at present of knowing.

When I was in England, and people told me of the clearness of the air in other countries, I did not understand them; that is, I did not appreciate what was meant. I had been accustomed to certain views of landscapes in nature which I had seen under a hundred variations of light and atmosphere, and I simply concluded that "a very clear atmosphere" meant the same as in England, on a clear day; that the clearness spoken of, in fact, did not so much refer to a different quality in the air to that well known in England, but that it simply meant that the air was always as clear as when at its best in England. There is, however, in New Zealand a different quality in the air, or, perhaps, more correctly speaking, a more exalted condition of the quality of clearness, than anything I ever saw in the old country. Christ Church is situated on the border of a great plain, at its narrowest part about forty miles in width. The plain is bounded on one side by the sea, and on the other by a chain of mountains. The plain, however, itself has a gradual slope, being about twelve hundred feet above the sea level at the foot of the mountain ranges, and gradually sloping down to the sea level at the water line. The mountains rise suddenly from the plain, and reach various elevations, from two to six thousand feet; farther back are other ranges, from five to ten thousand feet above the sea level. I give these particulars somewhat in detail, because they will serve to make what I have to say more intelligible. These mountains, then, are visible from Christ Church; but, if that were all, it would not be saying much, as, of course, objects might be visible in England if their heights and positions relative to the observer were the same. This is not all, however, for not only are the mountains visible, but all the details on them. You see where the snow lies, and where it does not; you see in the morning light where the gullies and ravines run into the main chains; you see the spurs and minor ridges, and can make out clearly the outlines of tracts of bush, &c.; the paths of the rivers coming down, and the positions held by the glaciers, are also clearly distinguished. Now this, I say, evidences an atmosphere possessing greater qualities of clearness than is ever experienced in England. It is simply impossible for a new-comer to these parts to believe that the nearest of the mountains, seen with the clearness I have attempted to describe, is forty miles distant; and that others, apparently almost as near, are fifty, sixty, and some seventy miles away. If any of my readers will get a map of England, and set off on a slip of paper forty, fifty, or sixty miles, and then hand it about in various positions, they will get a better notion of what I am writing about. I am perfectly familiar with the appearance of Calais heights as seen from Dover, and I can confidently affirm that Mount Somers, which is sixty-five miles distant from here, can be seen often quite as clearly from hence as Calais from Dover. Mount Somers is about six thousand feet, I believe. Now, the question is, if Calais cliffs could be pushed up to six thousand feet instead of, perhaps, six hundred or less, would they be then seen as clearly from Gravesend as they are now seen from Dover? And this brings me to the point I wish to raise, namely, can any of your scientific readers suggest a plan for observing accurately what is the exact amount of clearness possessed by the atmosphere at any given time, so that the observations could be made in various places, and ultimately compared? At present we measure with exact precision the weight, moisture, and other physical qualities of the atmosphere; but I have not seen any description of apparatus or suggestion of method by which its clearness can be determined. If any of your readers can suggest any

method likely to ensure a fairly exact result, I should be happy to make a set of observations in this country for comparison with those which may be taken elsewhere. It will be seen at once that any plan for making such observations as these must be one capable of being carried into effect in such a manner that the result shall be easily comparable with those obtained by other observers. Such a comparison of results obtained in various parts of the world would be interesting, if not valuable.

Shortly after landing here I met with a curious instance illustrating the above remarks. There is a small range of hills apparently close to the town (between it and the port). I often said to a friend, "Let us go and get up on those hills," whereat he laughed; he thought it ridiculous that I should insist on wanting to do a twelve-mile walk, whereas I thought him ridiculous for making any difficulty about a four-mile stroll of an afternoon. One day I determined to go alone, and found it over five clear miles to the foot of the hills, and they don't look above a mile and a half or two miles off—that is, judging by what I had been accustomed to all my life. I should have said the hills were that distance on account of the apparent clearness of the bushes, rocks, grass, &c., seen on them. I mentioned the effect to several old colonists, and they all agreed that though such appearances had now become quite natural to them from custom, at first they were all in like manner deceived by the clearness of the atmosphere. The question is, can any of your readers suggest, not a remedy, but a means of estimating exactly the boon? Can they, in short, suggest an accurate means of gauging the clearness of the atmosphere?

PHOTOGRAPHING CHILDREN, ETC.

BY FORESTER CLARKE.*

ONE of perhaps the most difficult things under all circumstances that we are called to do, is to make negatives of children from two to four years old—these sly little youngsters, of just that age too large to sit in a high chair or on its mother's lap, suspicious of everything new, and frightened to death at the sight of a head-rest, perfectly understanding everything that is said or done, but have not the least idea of obeying, or rather, cannot be made to mind for love or any number of promises of money, candy, dolls, or trinkets, of the thousand-and-one kinds lied about every day in the week. And is it not surprising, when we stop to think of it, how really ignorant most people are in such things, what ideas they have in regard to their children's pictures, and yet how very confident they are that they know fully as much, if not a little more about it, than the photographer himself?

If a child has lived to be two years old, especially if it is the first one, it is too large to be taken sitting, and they have decided to have it taken standing, and if the lady brings with her an aunt or grandmother, they are sure to advise with her rather than ask the photographer anything about it. Sometimes three or four extra hands come along, and all expect to come right into the operating room "and help." In my own practice I have often found it more work to get rid of the extra help, and get the room quiet, than it has been to make the child's picture.

These aristocratic people have an idea that they are perfectly competent to assist, and they do not choose to be slighted. I have had more trouble of this kind from lawyers' and doctors' families than from any other trade or profession.

One doctor—a very high-minded and high-strung Englishman—wife, and child, came into my rooms some time since, walked into the dressing-room, laid off their things, came right into the operating room. The wife proceeded to place the child in position, and the doctor, with the idea of making himself useful as well as ornamental, looked around until he got a bell or something else, and

* *The Practical Photographer.*

then, with all his elevated notions, his English, &c., commenced parading himself up and down in front of my camera, to interest the child, while the mother was holding it. I spoke to him quietly, told him that was all unnecessary, we should do much better if everything was still until we were all already, and added that I felt quite confident that I was able to do the work; but he took no notice of me or my suggestions. I gave him several hints to sit down and make less show, but he did not take it in that way. I then said, "Doctor, please be seated; if I need your assistance, I will call on you." "But, look here, sir," said the M.D., "I want you to distinctly understand, sir, that this is our child, sir; and we want it taken just as we want it, sir!" "Well, now," said I, "when I come to your office and need your services, I will tell you exactly what I want, and then I expect to follow your directions; but here you come to my rooms for my services; ought I not to have a chance to work without any interference?" He did not accept my position at all; would not notice it; said, "We came here expecting to, at least, be treated decently, but, on the contrary, you have been insulting, impudent, overbearing, and saucy, ever since we came into your rooms." I quietly replied the whole charge; he was never worse mistaken in his life, &c.; and he finally settled himself on a neighbouring chair. And I made the negative so that they were quite well pleased with the picture; but I have not yet had occasion to call at his office to engage his services.

One of the 'cutest little tricks that I have learned, with most of the little fellows that are able to understand at all, is: first, to be careful that the mother does not get a chance to give the child a lecture on behaviour in the reception room—a most detestable practice. Who has not been most fearfully annoyed in finding the little things standing or sitting as stiff as little posts? And then you have first to undo all they have done by talking to them, before you can possibly put them in any half-way decent position. Tell the parents not to say anything to the child about pictures; find out its first name, so you can address it in a familiar way; have your room and plate all ready; the mother and child only come into the operating room. Now, mamma, let me do the talking. "Well, Johnnie, you came in to see mamma have her picture taken, didn't you?" "Yes, sir." "Well, mamma may have a seat right over here by the side light, and you, Johnnie, may come and see me fix her head in this little rest;" and he has a chance to see it all. "Well, now Johnnie, you climb right up here where you can see me—that is a nice place; I will tell you how I sit my little boy when he comes out here; sometimes he puts one foot right under the other knee—splendid; you are such a nice little fellow that you may take my little boy's rest, and have your head rested just like mamma's, there now, we will see if we can see mamma through here." "Oh, yes!" "Now, sometimes I count one, two, three, four; let's try that just once more, or perhaps with music." If the child is one that can be talked to at all, I hardly ever fail of getting most any position I want, and the little fellows seem pleased enough to see mamma get her picture taken.

Correspondence.

NOTES ON CARBON.

SIR,—It is gratifying to find M. Lambert so successful with carbon in America. A great enameller, on his return from the Philadelphia Exhibition, gave it as his opinion that the climate was too hot. Perhaps it was, with two process-vendors in the field, one a *burnt-in* man, the other claiming absolute permanence by a process which is no secret.

The Chromotype process is simple and clean, the material inexpensive and of the best possible quality, the results superior in colour to any enamel I ever saw, and it can be worked in the hottest weather of America. It is quite true that in this country some of M. Lambert's pupils found

many troubles when the hot weather of last summer came upon them. It is quite true that the most eager to abandon silver printing had to return to it, in the high pressure of business and the high register of the thermometer; but it is also true that a goodly number of carbon men had become so familiar with the process that they found no trouble with hot weather, or any other of the dozen difficulties found by alarmists. It will put new fire into the breasts of those who are a little faint-hearted, and of those who too frequently look back to their old love—silver—instead of trying to unlearn it, to know that the Americans are also recognizing the improvements of M. Lambert.

The Autotype Company are now to give extra facilities of intercommunication amongst licensees, so that any seeming difficulty in the process can be explained, and the faults in manipulation corrected. This is indeed a great concession by the Company, and likely to prove of mutual advantage. It is wasting time for "One Anxious to Learn" waiting to pick up the process. There is only one legitimate and honourable course to pursue, and that is to come down with the dollars, secure the right to good material, a course of instructions where the process is successfully carried on, and every reasonable difficulty met with explained away, through the Company and their licensees. All those anxious-to-learn gentlemen may "pick up" good things in your able paper about carbon, but it is the interest of M. Lambert's licensees to keep a few good wrinkles to themselves. The great discussion at the Photographic Society's meeting the other week clearly proves that the process is a success, but nothing could be picked up there—not a hint. I cannot understand how a man could go round giving demonstrations, even "for a fee," and make the lame excuse that his tissues was too old. If the demonstrations were a failure, "Another One Anxious to Learn" should have withheld the "fee;" indeed, I don't see why he didn't teach his printer to do carbon himself, and save the "fee." I am rather afraid there are too many anxious to learn, but only at the expense of threepence a week for your able and enjoyable PHOTOGRAPHIC NEWS. The Chromotype process, as perfected by M. Lambert, is the result of an expenditure of capital, labour, and research incalculable: little wonder, then, that those who work the process don't tell everything. It is penny wise and pound foolish to linger. Go in for carbon, I say; even the enlargements will refund you in a short time. The Edinburgh Photographic Exhibition was very successful, but I was surprised to find so little carbon work by resident photographers, and greatly displeased to see a very bad silver print—that is to say, a faded print—awarded a medal. When in Edinburgh, I learnt that there were only two photographers who had the right to practise carbon printing under Lambert's patents. No wonder poor Edina is far back in permanent printing when this is the case. It is too hard on Scotland to have her chief city photographers kept out of a good thing in this way; it is all our interests to reform this if we can. How are we to help the photographers of Edinburgh?—Yours, truly,

JO. VESTRIA.

PHOTO-TINT.

SIR,—Our attention having been called to an article in the YEAR-BOOK entitled "Photo-tint," by Mr. E. Cocking, in which his ingenious method of tinting silver prints is described, we think it desirable to explain to your readers that this bears no relationship to the process of mechanical printing in permanent ink which we ourselves have recently introduced under the name of Photo-tint, and for which the bronze medal has been awarded at the Edinburgh Photographic Society's Exhibition. We need scarcely say, that at the time of our adopting this as a distinctive name for our method of printing, we were quite unaware that it had ever been used to describe any other.

—We are, sir, your obedient servants,

R. J. EDWARDS AND CO.

61, Fleet Street, E.C., January 25.

[It is unfortunate when the same name is adopted to indicate two distinct processes. Mr. Cocking's pretty results were described some years ago under the term Photo-tint; but, as he observes in our YEAR-BOOK just issued, no attempt has been made to follow up the idea, and hence the name was not generally familiar; and it is easy to understand how, in ignorance of its former use, it was adopted by Mr. B. J. Edwards, to designate his very excellent results in photo-collography.—Ed.]

NITRATE OF IRON DEVELOPER.

SIR,—Dr. Diamond having, in the YEAR-BOOK OF PHOTOGRAPHY, expressed his willingness to afford "further information" to any of your readers on the use of the nitrate of iron developer, I shall esteem it a favour if he will kindly give the precise method of making developers which will produce a dead silver surface, as also the modifications referred to in his communication. He will, perhaps, also state the strength and acidity recommended for the silver bath solution. I have made some beautiful pictures by following the system published some years ago by the late Mr. Sutton, and can quite confirm Dr. Diamond's statement as to their permanency over, at least, a period of twenty years.—I am, sir, your obedient servant,
Ryde, January 23rd. F. M. Z.

HEALTH OF PHOTOGRAPHERS.

DEAR SIR,—The suggestions contained in the quotation from the *Philadelphia Photographer*, as to the precautions advisable to be taken by photographers to guard against disease, are well worthy the consideration of the profession; but I fully believe the greatest evil is the very careless and irregular manner in which many operators take their meals. It is a common thing for them to be engaged in the studio from morning until evening, working in an unwholesome atmosphere, and under a hot sun, the only sustenance taken during the whole time being, perhaps, just a light luncheon. I venture to say, that no constitution can stand against this for many years; and my own opinion is, that if persons engaged in photography were always to take a substantial meal in the middle of the day, we should hear less of the cry that it is an unhealthy occupation.—I am, sir, yours truly, ALFRED HARMAN.
79, High Street, Peckham, February 1.

Proceedings of Societies.

WEST RIDING OF YORKSHIRE PHOTOGRAPHIC SOCIETY.
The ordinary meeting of the above Society was held at the Commercial Hotel, Bradford, on Monday, the 8th inst, Mr. SMITH, the president, in the chair.

The minutes of previous meeting having been read, and received confirmation, Mr. John Lightfoot was elected a member.

Mr. BRAYBROOK then read a paper on "Carbon Printing," which will appear in our next.

The PRESIDENT remarked that it was not the first time the Society had devoted an evening to carbon printing, as Mr. Greaves had, on a previous occasion, given a practical demonstration of the process. The subject was an interesting and important one, and he was anxious that all the members would, as far as possible, take part in the discussion.

Mr. WORMALD LUDS said that he had not had a large experience in carbon printing, but from what he had done he did not intend to issue any more of his larger pictures in silver, as he could get a superior result in carbon, as well as insure permanency. He then handed round a number of prints in carbon, 26x21, with matt surface, which were of fine quality, and much admired.

Mr. SMITH thought the length of time allowed for drying the prints in the final transfer was unnecessarily long; providing the moisture could be got rid of, he did not see that any particular time was necessary, and suggested that instead of placing the whole of the print under pressure, it should be put in some sort of frame, which would keep down the edges, and allow the air to have free access to the back of the picture, thus facilitating the drying of it.

Mr. ILLINGWORTH was of opinion that a slow drying was best, but thought a good gloss could be obtained in a shorter time than had been stated to be necessary. The experience of the members varying very much on this subject, it was agreed to put the matter to practical test.—Mr. Sachs, representing the slow drying, would submit prints dried forty-eight hours; and Mr. Illingworth prints dried in the shortest practicable time—and the members would be able to form their own opinion.

Regarding the question of drying tissue,

Mr. HOWARTH asked if a current of pure air was necessary, or could gas be used to obtain the dry air requisite?

Mr. SACHS said gas was very objectionable, and should not be used.

Mr. WORMALD stated that all his tissue was dried by the aid of a Bunsen gas burner, and he had found no harm to result.

Mr. COCKING was of opinion that dry air, pure, was much better than using gas, and mentioned that he had adopted a method which might be new to some of the members, that of pinning the tissue with its back round a roller of plaster of Paris, which rapidly absorbed the moisture, and allowed the tissue to dry very quickly, and he suggested the use of the plates of plaster for placing between pictures, when mounted for full gloss, for the purpose of absorbing the moisture from the mounting boards.

After some further conversation, a vote of thanks was passed to Mr. Braybrook for his paper, and the proceedings terminated.

Talk in the Studio.

WEST RIDING PHOTOGRAPHIC SOCIETY.—At the next meeting of this Society, to be held Monday, February 5th, at the Commercial Hotel, Tyrral Street, Bradford, Mr. J. Crosthwaite will read a paper on the "Dusting-on Process."

LIGHT, AND SCARS FROM SMALL-POX.—Mr. Isaac Gregory, F.R.G.S., Principal of Merchants' College, Blackpool, calls attention to the fact that "pitting" in small-pox is chiefly due to the actinic effect of light reaching the sufferer's face, and recommends the use of actinetic yellow blinds in the patient's room.

STAGNATION IN PHOTOGRAPHY.—Dr. Vogel, writing to *The Philadelphia Photographer*, says:—"Though war is only as yet approaching, the dulness of business here is already very great. The ateliers are empty, and some are closed entirely. From all sides we hear complaints. But I must say that I found the decrease in trade, in a great many respects, far worse. Dr. Weissenborn, an eminent member of our society, finds the cause of this stagnation to be, that the public are surfeited with photographs. The public is tired of the carte-de-visite and cabinet photographs, and he believes that we ought to try something new, in order to bring the business up again. He proposes, as a new idea, transparencies in carbon. They can be produced easily, look handsome, and bring money. Besides that, he recommends the production of more portrait stereotypes. The propositions have something in their favour, and perhaps not only for Germany, but also for America, where there is now at least more attention paid to the carbon process. Nevertheless, we ought not to overlook that the cause of this quietness in business is not only the surfeit of the public with photographs, but the present general business calamity over the whole world."

PHOTOGRAPHIC SALVAGE.—Mr. J. Walter, writing from Lyme Regis, Dorset, says:—"Perhaps the accompanying item of news may be of interest to some of your readers; if so, it is at your service. During the past week, amongst a variety of articles washed ashore and picked up at sea, within a few miles of this place, was a case of collodion, containing forty-four pints of plain collodion, but labelled collodinum. There had probably been fifty bottles, as some were broken. Each bottle was corked, and a piece of bladder tied over the cork, whilst the stopper with which each bottle was provided was tied to the neck. A small quantity was handed to me by the Collector of Customs (who is also Receiver of Wrecks) for testing. I found it quite uninjured by salt water, none of which had entered the bottles, and on adding the usual proportion of Mawson's Iodiser, as supplied with their collodion, it produced a rather thin but very sensitive collodion, with which, on a dull afternoon, I took a clear negative, full of detail, in ten seconds. The negative would have been better, probably, for a shorter exposure; but I was called away, and had not time to make further experiments. The whole will probably be sold in a week or two for salvage."

The Photographic News, February 9, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE INTERNATIONAL EXHIBITION FOR 1878—PHOTOGRAPHY AT THE THEATRE—GLUE WITHOUT GELATINE.

The International Exhibition for 1878.—The Paris Exhibition for 1878 should be a success. The German Government seems to have withdrawn its opposition—for a refusal to take part in the gathering practically amounted to this—and there is now every reason to believe that support will be forthcoming in this, as in every other direction. Probably the government at Berlin felt that the Exhibition would flourish without their aid, and hence they have hastened to appear virtuous while there is yet time. In this country the matter is being energetically pushed forward. Mr. Cunliffe Owen, the Director at South Kensington, who has been nominated Secretary of the British Commission, has proceeded to Paris, and declared that no pains shall be spared on the part of this country to render the International Gathering of 1878 as popular as possible in this country. He was authorized to state that His Royal Highness the Prince of Wales, the President of the Commission, had determined personally to use every endeavour to further the success of the undertaking, and that he should consider himself a working officer in connection with the affair. Under such promising auspices there can hardly be a doubt as to the well-being of the next International Show, and indeed the number of applicants for space already registered by the officials in Paris has exceeded the most sanguine expectations. We in this country hardly consider Paris a foreign city at all, from the circumstance, no doubt, that it can be reached from the capital as quickly as Edinburgh or Dublin. Such Englishmen as are not Cockneys by birth or adoption feel quite as much at home in Paris as they do in London, and hence a journey to the metropolis of France has come to be regarded as a very ordinary affair indeed in this country. In these circumstances an International Exhibition in Paris is looked upon by most Englishmen as convenient to visit as one in London, and is certain to attract as large a number of visitors from this country. In the case of less wealthy exhibitors, too—and we may include photographers in this class—there is pretty sure to be far more in Paris than can be gathered together in any other capital, by reason of the general come-at-ability of that metropolis. Our brethren who visited the 1867 Exhibition in Paris will remember that there was a better show of photographic work there than had previously been brought together. Spain, Italy, Austria, Germany, Switzerland, Belgium, &c., were better represented than was the case in our Exhibition, for the simple reason that the exhibitors had not so far to send. For the same reasons the Philadelphia Exhibition was so sparsely represented by less important exhibitors, for it was scarcely to be expected that men who had but a show-case or two to send would take the trouble to forward them all the way beyond the Atlantic. As our Paris Correspondent, M. Lacan, has already intimated, a very impartial manner will be adopted for choosing the juries connected with the Photographic Section. One jury—the Hanging Committee, as it might be termed—has already been chosen, the members being men well known to French photographers, half the number being taken from the lists of the French Photographic Society, and half from another official body, termed the *Chambre Syndicale*. This jury will decide upon the admission and hanging of all photographic work, but when they have done this their functions will cease. The award of honours will be delegated to a different jury altogether, which will be chosen by the exhibitors themselves, foreigners being represented in accordance with the number that may take part in the gathering. So far, therefore, the arrangements for the 1878 Exhibition may be spoken of with praise.

Photography at the Theatre.—We have already alluded to the debt which scene painters and costumiers of the theatre owe to the photographer, and in a new piece just produced in Paris, called *Dr. Ox*, the theme of which is taken from one of Jules Verne's wonderful stories, and the music supplied by Offenbach, we are told that photography has been employed more largely than usual in rendering the *spectacle* as truthful as possible. The scenes in some cases are accurately painted from photographs, so that the public have before them something more than fantastic sketches. In like manner, pictures of costumes taken in different parts of the Netherlands have served as a guide in designing the brilliant dresses worn by the *dramatis personæ*. In one of the London theatres lately, a very fine view of the *Mer de Glace*, and of the Lake of Lucerne, also attracted much attention, which had been so truthfully delineated that in the first picture the characteristic masses of ice were as perfectly rendered as in the photograph itself.

Glue without Gelatine.—Photographers are quite aware that the glue they employ often varies in quality and in adhesiveness. If they are curious to know why this is, an excellent paper on its manufacture appears in *Dingler's Polytechnisches Journal* which throws a good deal of light upon the subject. Steam, it appears, is generally used in its preparation, and if this heating medium happens to be of too high a pressure, then the glue prepared is of inferior quality. Indeed, M. Terne finds the inferiority of the product is directly proportional to the pressure of the employed steam, until at length, if the operation be carried too far, all the gelatine is destroyed. Thus, it appears, we may purchase glue which is altogether innocent of gelatine. A material, we are told, which, at a pressure of twenty pounds per square inch, yields a tolerably good product, given at a pressure of thirty pounds or over (the time of boiling being in both cases the same) a glue, if it may be called by that name, which is perfectly white, and does not contain an atom of gelatine.

THE COLLODIO-BROMIDE EMULSION PROCESS APPLIED TO TRANSPARENCIES, AND ENLARGING WITHOUT A NITRATE BATH.

BY WILLIAM BROOKS.*

Stereoscopic Transparencies.—It is to be regretted that stereoscopic pictures are so little in demand at the present time; I allude both to the ordinary paper slide and the transparency on glass. The latter, to my mind, if properly made, is one of the most beautiful productions of the photographic art. I attribute the falling off in the demand for the ordinary paper slide (to be viewed by reflected light) to the enormous amount of trashy stuff the market has been glutted with—looking abominable out of the stereoscope, and much worse in it.

The great drawback to the glass transparency, I think, has been its price, the best ones being made by a very tedious process on a film of albumen, which is liable to fade. I do not think that at the present time a good slide can be obtained at less than five shillings and such a price is far too high for persons of limited means to purchase. A moderate collection—say fifty slides—at the price mentioned would come to a good round sum, more than many could afford, and therefore they go without them altogether. The great cry of photographers at the present day is for something new that would create a demand; now, this branch of the art is one that has been but little worked, and the little that it has been worked has been done in a very expensive way. I think the generality of photographers are very conservative, and will not do anything unless it can be done with the nitrate bath, &c.; for if one happen to mention anything about emulsion work, dry plates, and the like, they begin to pull a long

*Read before the South London Photographic Society.

face, and say they don't believe in it, and still go on in the old jog-trot sort of way.

I have tried the nitrate bath, iron development, and pyro development for stereoscopic transparencies, and the results have always been cold and hard, with inky tones, and very coarse. I can find nothing for their production like the emulsion process worked in the way I shall describe, and show you the results of my experiments. I am able to obtain all the warm tones exactly the same as we see in our well toned silver prints—a nice, rich, warm chocolate brown, rivalling those I before mentioned, as produced on the albumen films; and they can be produced and retailed in the market at about two shillings and sixpence each, leaving a good margin for profit. If a good demand sprang up, they could be reduced still lower in price, which, I am sure, would cause a revival of the stereoscope. At the present time there are thousands, and, I may say, tens of thousands, of stereoscopic negatives stowed away in the plate boxes of the photographer, both amateur and professional. There are several methods by which transparencies can be produced.

No. 1.—Printing by contact is all very well if only one or two be required; but for commercial purposes it does not answer, as the negative becomes damaged in spite of every care that is taken in dusting both negative and plate, although contact printing produces very fine results. At the same time, to produce the subject in its proper position two glass plates have to be used besides the one that carries the collodion film, which has to be cut and the halves transposed, to bring them into their proper position (presuming the original negative has been taken with a binocular camera). In printing by contact the glass used must be perfectly flat and clean. In this case the plate must be albumenized with—

White of	1 egg
Water	1 pint

The plates can be either immersed in it, or coated with it while still wet, and set aside to dry. My reason for albumenizing the plate is, that in contact printing, if the film get punctured with small holes, it will sometimes crease up during development and spoil the plate. After the plate is thoroughly dry it is coated with a thin collodio-bromide emulsion, known as "washed emulsion," and set aside to dry, film outwards. I may also mention that it requires a little knack in coating the plate to avoid crapy lines. A pool of emulsion is poured on one end of the plate, allowed to flow downwards in a wave, and poured off at one corner, when the plate is rocked once or twice—not more—then bring the plate into a vertical position, and by this means, if the emulsion be in good condition, all crapy lines will be avoided.

After the plate is dry it is placed in contact with the negative in an ordinary printing-frame, and exposed to the light from one to three or four seconds, according to the density of the negative and intensity of the light. Care must be taken, in removing the plate from the negative, that it does not grate, as the film is very tender. Methylated spirit is now poured over the film and returned to the bottle, as in the case of collodion, and allowed to soak in for a minute or two. I do not hold with the plan of diluting the spirit, for if diluted it does not do its intended work so readily, and the development is more difficult; the film requires to be restored to its pasty condition as much as possible. If a quantity are being done, the best way is to use a dipping-bath with a cover.

On being removed the plate may either be washed under a tap, or immersed in a dish of water till all the greasy lines are removed, and the water flows freely over its surface. The plate is then placed in a little shallow glass tray, similar to that described by me in the *British Journal of Photography* for 1876, page 115. I find it very handy, and the progress of development can be readily seen, without any fear of its falling out when holding it up to the light to

look through it; it can be turned bottom up, yet sticks as tightly as wax.

I prepare stock solutions, which keep in stoppered bottles, thus:—

P.—Pyrogallie acid (English) ...	96 grains
Absolute alcohol (a.g. 805°) ...	1 ounce
B.—Bromide of potassium ...	15 grains
Water ...	1 ounce
A.—Liquor ammonia ...	40 minims
Water ...	1 ounce

After the plate has been sufficiently washed in a clean measure, take five to ten drops of solution P, three drops of solution B, one drop of A, half an ounce of water, and pour this over the plate. If properly exposed the image will begin to appear in about half-a-minute. The above quantity is for stereo size. If the image appear too quickly, add a drop or two more of solution B; if it comes up slowly, add another drop of A. When the developer apparently ceases to act, add one or two drops at a time of each of solutions A and B, which will give intensity. This system of development is the ordinary method adopted, but gives for transparencies a rather smoky colour when viewed by transmitted light. I find that I am able to get very pleasing tones, similar to those we have in our well-toned silver prints. Instead of using plain water, I use a solution of acetate of soda, which I keep as a stock solution—

Acetate of soda ...	4 drachms
Water ...	1 pint

This not only seems to impart a better tone to the picture, but it also appears to act as an accelerator. I also use a solution of phosphate of soda, if I wish to have a sepia tone. The phosphate solution is used in place of the acetate of soda solution, and in the same manner:—

Phosphate of soda ...	2 drachms
Water ...	1 pint

I will now pass round for your inspection specimens developed by both methods, which will fully corroborate what I have just stated. I have no doubt that using other neutral salts will give a greater variety of tone. Should the tone appear a little too warm in colour I give a slight intensification with—

Pyrogallie acid ...	8 grains
Citric acid ...	1½ grain
Water ...	1 ounce

with a drop or two of a ten-grain solution of nitrate of silver, as in the wet process.

I must not omit to add that the alkaline developer should be well washed off, and some dilute acetic acid flowed over the plate to neutralise all traces of ammonia to avoid stains. If black tones are required, give a much shorter exposure, and develop by either of the before-mentioned methods, not carrying the alkaline developer too far, but bring it up to the required density with the acid pyro.

Fix in a solution of—

Hypo ...	1½ ounce
Water ...	1 pint

Well wash, and varnish with a varnish made of white, hard varnish thinned down to the proper consistency with methylated spirit, adding about two drops of castor oil to prevent its splitting in time to come.

Instead of using ground glass—a good sample adding very much to the cost—I use an ordinary matt varnish diluted with ether, as it gives a much finer grain, and is very inexpensive, which must not be lost sight of. The slide is now ready for mounting.

No. 2.—Instead of printing by contact, use a non-distorting lens, and make the transparency in the camera in the ordinary way, using the plate in the dry state, as in the preceding method. The transparency also requires cutting for transposing; the best system, however, is to cut

the negative in half and transpose. By copying with the camera we also have the advantage of either reducing or enlarging the subject according to the amount of the subject to be included, and a mask put in the dark slide in front of the plate makes a much neater job. The development is the same as in printing by contact.

No. 3.—The plate is coated with emulsion, but instead of letting it dry, put it in a dish of water until all greasiness has disappeared, and expose in the camera while still wet. No substratum must be used in this instance. By this method the tones are different, giving a greenish hue. When fixed, washed, and dried, it is coated with a solution of india-rubber in benzole, and then with a rich collodion, alternately, several times, until a good rich film is obtained, similar to the Warnerke films. In the last coating of collodion I saturate it with white wax; this dispenses with the use of the ground glass or matt varnish. When perfectly dry the film will readily peel off; then it is cut and transposed, gummed at one edge of a cut mount, and bound between two pieces of glass. This system is more tedious than the former ones. I now pass round a slide made by this method.

Lantern Slides.—These can either be introduced by contact in the same way as the stereo slides (and developed also in a similar manner), or they can be copied from the negative in the camera, and enlarged or reduced at pleasure. At the last meeting of this Society, being the popular lantern evening, the whole of the slides I exhibited were made by this process. Most of you saw the kind of image they produced on the screen. Several members having wished to examine the slides themselves, I now take the opportunity of complying with their request. In making the slides it is better that they should be developed by the alkaline developer alone; and, as it is an important point to keep the lights of the picture bare glass, before fixing flood the plate with—

Aoetic acid (Beaumont's) ...	2 ounces
Water... ..	8 "

This appears to take up any deposit on the surface that may have taken place during the development. I have heard several complain that slides produced by this process looked cloudy. Varnish with diluted white hard spirit varnish, the same as mentioned in the former part of this paper.

Transparencies for Decorations.—These may be produced by the same process. I will leave you to judge how far I have succeeded by the specimens I have brought with me. I find that frames can be purchased in brass with chains for suspending these for window decorations, which answer the purpose admirably.

Enlarging without a Nitrate Bath.—If a negative be taken with the intention of producing an enlarged negative, I prefer taking the original on one of the dry plates before mentioned, using only alkaline development. If acid pyro and silver be used, it causes a granular deposit. It is true the granules are small; but when enlarged up to several diameters they are very offensive, as we all know. If the negative is to be printed from, and not enlarged, I quite agree with Mr. Woodbury that it is best to intensify with pyro and silver, the resulting print having a true dry-plate effect. The effect of this pyro and silver intensification is that it produces a very fine stipple, which gives softness, but will not do for enlargement; and I think this is why enlargements look coarse.

I prefer to make the transparency by contact, and develop by the alkaline method only. The enlarged negative is made in the ordinary way from the transparency, instead of using a plate prepared in the bath. The plate is coated with an emulsion, and immersed in water until the water flows freely over its surface; it is then ready for exposure. I have prepared an enlargement by this method, using alkaline development, followed by pyro and silver, to bring up the intensity. I have brought with me the transparency and enlarged negative, also some prints from the latter.

You will find there is not any coarseness, although I have enlarged it up to three and a-half diameters, and I now submit it for your inspection.

CARBON PRINTING.

BY T. R. BRAYBROOK *

THERE have been so many and such ably-written articles on this subject, that there appears to be very little room for me to say anything; but if you will give me your attention I will try to throw out a few hints that, at the least, will bring about a discussion from which we may all profit.

When a man first starts carbon printing (and there are a great many have started who at first cried the process down) he must determine within himself to overcome all obstacles and failures, of which he will find a great many; and he must bear in mind that it is only by practical working, day after day, that he gets to understand the process thoroughly. You must not begin by falling out with your materials until you have given them a thorough good trial, for in nine cases out of ten you are wrong, and not the materials. Your tissues may dry unevenly, or be insoluble altogether, if the room you dry it in is not in a proper condition. A room with a current of dry air passing through it is the best. You do not require heat, although in wet weather you must have a little. You can get the desired current by placing a ventilator, having a revolving top, in the roof of your drying-room. You will find by this method of drying that your tissue will hang straight from the lath you pin it to, and dry evenly, not curling and cracking, as it is sure to do in an over-heated room or where a great fire has been left burning. If you have only one piece of paper to dry, tie a piece of string across the mantelpiece, and hang the tissue in front of the fireplace, so as to get the current of air that passes from the doorway up the chimney. There is yet another advantage from the tissue being dried in this way: it is more sensitive than it would be if it had been dried rapidly.

Sensitize in a solution composed as follows:—

Bichromate of potash ...	3 ounces
Water	100 "
Ammonia	1 drachm.

The waxing solution is composed of five grains of wax to the ounce of benzole. Care must be taken that the wax and benzole are both pure; if they are not, your prints will be so very fond of the glass that they will not leave it. A plate that has once been used does not require cleaning again, but only the collodion scraping from the edges, and re-waxing.

To develop, always use two baths. Immerse the plate in the first with water just warm enough to remove the paper from the printed pigment; then you may pass your plate to the next bath, the water being a little warmer, to finish the picture; but take care not to hurry the development, or you will lose the half-tones and get chalky prints. It is better to over-print a little rather than under-print, as you can reduce with hot water; but you cannot add to the density.

After fixing, drying, and transferring, let your plates remain under pressure, between sheets of blotting-paper, for an hour or two at the least. I generally leave mine for four or five hours to absorb the moisture from the transfer, and to prevent the transfer-paper moving during mounting, as it is apt to do if you mount too quickly after transferring.

I mount in the evening, and leave the plates under pressure until the next morning. I then rear them up to dry, taking care that the room be not too warm, or else they will leave the glass before they are thoroughly dry, and will, of course, have an uneven surface. To obtain an even and highly-glassed surface, the prints should be from thirty-

* Read before the West Riding of Yorkshire Photographic Society.

six to forty-eight hours drying. I find that the longer they are drying, the higher the gloss and more even the surface. Not that, personally, I like very highly glazed pictures, but the public do; and as they have to pay for them, it is, of course, to our advantage to try and get it, and so please them.

Now for the last, but not least, of the difficulties of carbon printing—viz., vignetting. This, at the best, is a difficult task, and requires much practical experience, as you cannot look and see how the picture is going on, as you can do in silver printing; but with a negative having a light and suitable background you can get a very good vignette with brown paper and cotton wool, having a little piece of tissue paper over the brown, the same as in silver printing. You must, of course, move the frame about a good deal, because carbon prints are so much sharper than silver. For large work, cut out three or four shapes a little larger than one another—say an inch and a-half—take off the smallest when the picture is about half done, the next later on; and so on until the picture is printed, and you have the size you want. You may in this way get a very soft vignette.

In conclusion, I would say the process is so thoroughly practical that any photographer should be able to work it, provided he gives his mind to it, and has proper convenience and premises. If he have not the latter, he had better leave it alone, for it cannot be worked commercially in a sink, with one or two porcelain dishes and a kettle, and paper dried in the operating room, or in a room where a great roaring fire has been kept all day. This process is of great value in dull weather like the present, as you can do from fifty to one hundred per cent. more work than in silver, with the crowning advantage of all—namely, your prints are permanent.

PHOTO-COLLOTYPE PRINTING.

BY M. T. H. VOIGHT.*

It is not my intention to refer back to the early experiments with bichromated gelatine made by M.M. Niepce de St. Victor, Fox-Talbot, and others, neither to describe the more improved process of M. Tessié du Motay. I merely desire to put before the eyes of those interested in the matter, some details of the processes which have been practised since M. Albert, of Munich, brought forward his improvements, and rendered collotype printing an industrial art.

Everybody is perfectly aware that gelatine impregnated with bichromate of potash possesses the property of transforming itself, on exposure to light, into an insoluble mass, which has lost the property of swelling, like ordinary gelatine. If a film of bichromated gelatine is spread upon a substratum and dried, and then a portion of it is exposed to light for a certain period, a second part for a less period, and the third completely protected against luminous action, a surface will be obtained which, when moistened with water, will take printing ink in a graduated manner.

By passing over this film a leather roller charged with lithographic ink, the parts which have not been acted upon by light, by reason of the water that they absorb, will not take up the ink. Those slightly touched by light rays will permit ink to adhere in a slight degree; while such portions of the film as have been thoroughly acted upon by light will become quite black, because of the amount of ink that attaches to them.

It is upon this circumstance that photo-collotype printing is based. In the foregoing experiment we suppose things to happen as they do in lithography. It is, nevertheless, a recognized fact that the ink does not adhere with regularity to the portions of surface influenced by light if the film contain a greasy body or resinous matter. It is from this principle that the old and complicated process of M. Gémossier, published in 1869, proceeded.

* *Bulletin de la Société Française.*

The undermentioned solutions should be separately prepared:—

1. Of gelatine, 8.75 grammes are dissolved in 150 grammes of warm water.
2. Of isinglass, 3.75 grammes are dissolved in 90 grammes of boiling water.
3. Of white of egg, beaten to a froth, 60 grammes are dissolved in other sixty grammes of filtered water.
4. An aqueous tincture is prepared of—

Myrrh	2 grammes
Ammoniacal gum	0.75 "
Liquorice-root	3 "
Manna	0.75 "
Cane sugar	0.75 "
Milk sugar	1.50 "

The above being dissolved in 120 grammes of distilled water.

5. Bichromate of potash ... 4.75 grammes
- Bichromate of ammonia ... 2.75 "
- Water ... 120 "
6. Ammonia
7. An alcoholic tincture is prepared of—

Lupuline	3.75 grammes
Myrrh	3.75 "
Gum benzoin	2.25 "
Tolu balsam	1.50 "

8. A solution of nitrate of silver is prepared, made by dissolving 7.50 grammes of the salt in sixty grammes of water.

9. Iodising solution, made up of—

Iodide of cadmium	0.25 grammes
Bromide	0.125 "
One per cent. solution of gold	3 drops.

Before employment these separate solutions are mixed together in the following proportions:—

1. Solution of gelatine ... 120 grammes
2. Solution of isinglass ... 70.50 "
3. Solution of albumen ... 22.50 "
4. Aqueous tincture ... 22.50 "
5. Bichromate of potash ... 25
6. Ammonia ... 6 drops
7. Alcoholic tincture ... 7.50 grammes
8. Silver solution ... 2
9. Iodide and bromide solution ... 4

In the case of the Gémossier process, the plates only receive a single coating. Plates of glass of considerable thicknesses, with a ground surface, are covered with the prepared gelatine, and placed horizontally upon a tripod fitted with a proper levelling arrangement, and put into a drying box exposed to a temperature of about 50° Reaumur.

The plates thus coated, when dry and cold, are exposed under a negative, and thoroughly printed. With a little practice it is easy to judge of the progress of the printing by looking at the plate from below. After printing the plates are put into water, where they remain for half an hour, care being taken that the liquid is agitated from time to time. This operation is for the purpose of removing the chromium salts. This done, the plates are taken out of the water, and dried spontaneously; they are then covered by means of a sieve with a layer of flour one centimetre in thickness. Afterwards they are put upon an iron tripod, and placed in a stove, where the temperature reaches, after a while, 100° Reaumur, so as to coagulate the albumen; and, by softening the gums, to render them more adherent to the glass surface. The stove should be constructed like a pastry-cook's oven. The plate, allowed to cool gradually in the stove, is freed from its layer of flour, and is cemented, the image uppermost, by the aid of plaster of Paris, to a lithographic stone. It is then ready for printing.

Excellent results may be secured by this process, only it is very difficult to judge of the degree of heat necessary.

If the film is heated too much, it will not subsequently absorb enough water, and in consequence the whites take up a little of the ink on the roller being passed over the design; the shadows taking up a good deal, and the lights a little ink, the result is a flat monotone print. If the heat has not been sufficient, then the film will detach itself from the glass surface.

On account of these difficulties, the one-film process was abandoned, as well as the employment of resinous and saccharine matter, the uselessness of which was apparent.

At the present moment, with these exceptions, the foregoing formulae are made use of to produce a second film, the plates receiving first of all a preliminary film prepared in the manner to be described, for the purpose of assuring adherence without being obliged to employ a high temperature. Six grammes of gelatine are dissolved in 270 grammes of warm distilled water, to which is added 5.50 grammes of bichromate of potash. Then 112.50 grammes of white of egg are beaten, without any addition of water, to a stiff froth, and the gelatine solution, which must not be too hot, is added carefully; the mixture being allowed to stand for some hours, is filtered before employment.

The ground glass plate is covered with this mixture by the aid of a paper strip or glass rod, and the plate is subsequently dried at a temperature of from 20° to 25° Reaumur. This done, the plate is put into a printing-frame, the film covered with a piece of opaque fabric, and placed where diffused light can act upon it for about half-an-hour. Preparation of the plates to this degree may be proceeded with for some days before employment.

The operation is continued by applying to the plate the film which is to receive the impression, after the mixture which is to serve for this purpose has been warmed to a temperature of about 45° Reaumur, and filtered. The plate is maintained in a horizontal position in a water-bath (40° Reaumur), but it is moved to and fro a little, so that the coating already on the plate may become swollen and soft, and capable of being united in one homogeneous mass with the second film that has to be applied. This done, the plate is taken out of the bath of warm water, and, while the surface is still warm and wet, the liquid for the second coating is poured copiously upon the centre of the plate, which is inclined in turn towards each angle, so that a little of the liquid escapes, thus preventing any marked margin. The plate is subsequently dried in a stove at a temperature of 40° Reaumur.

(To be continued.)

CARBOLIC ACID IN THE CARBON PROCESS.*

It has already been pointed out in this journal that M. E. Friedlein, of Vienna, adds a small quantity of carbolie acid to the bichromate bath employed in the sensitizing of tissue, and this he recommends as a very useful precaution. In the December number of the *Photographische Monatsblätter*, the same gentleman once more refers to the circumstance, and points out the general advantage which accrues from the addition of this acid to all kinds of gelatine solutions employed in connection with photography. Particularly in the working of the Woodburytype process the addition of carbolie acid is to be recommended, for M. Friedlein has found that in the height of summer the gelatine becomes bad within two days—nay, even in one sometimes, if no precautions are taken to preserve it. A bad odour is expelled, and then the solution rapidly becomes limpid.

One per cent. of carbolie acid, added to a gelatine solution of a dilute character, was found sufficient to preserve the latter in an open vessel, winter or summer, and even when kept in a warm room for months; the only change perceptible being that brought about by evaporation, the surface of the solution becoming hard and parchment-like.

The addition of carbolie acid in pigment printing has

* *Photographische Correspondenz.*

one other valuable property. If a small quantity be put into the bichromate bath, it permits the preservation of the tissue in a sensitive condition for a week, and, at the same time, gets rid of many defects with which carbon printers are plagued. The only drawback is its somewhat unpleasant odour, but this is a slight disadvantage compared to the valuable properties with which it endows the tissue.

The following formula is recommended for the bichromate bath:—

Bichromate of potash	30 parts
Water	800 "
Fluid carbolie acid	1 part

and in summer—

Glycerine	6 parts
---------------	-----	-----	---------

The fluid carbolie acid is prepared by dissolving five parts of the crystallized carbolie acid by placing in hot water, and adding thereto one part of warm water.

NOTE ON THE CONSTRUCTION OF HEAD-RESTS

BY NELSON K. CHERRILL.

MR. EUCLID, in one of his ingenious problems, proves that two circles can touch each other internally only at one point. This is only a mathematical problem, but it is capable of a good many very practical applications, among which my present suggestion will, I think, be found of use among photographers.

A head-rest, as commonly constructed, consists in its essential features of a series of tubes or rods which slide into various positions through circular holes, and are maintained in their required positions by means of screws. This, viewed in the light of the proposition I have referred to, is, to say the least of it, bad engineering. Let us look at it. Here is the hole with the rod in it; they can only touch at A (fig. 1). To hold the rod firm, the screw is put in opposite: this holds the rod at *two places*, allowing it the tendency to lateral motion. To avoid this, the rod is usually made so

Fig. 2.

near the size of the hole as to fit almost tight, a condition which often involves difficulty in moving some parts of the rest, especially in the hurry of operating. If the rod were held at three places instead of at two—if, in fact, the round rod were put through a triangular hole, with the screw on one side of the triangle (fig. 2)—the construction would be far more perfect. It will be seen at once that a rod held thus would be more firmly fixed, with less pressure from the screw, than in the old plan. There is, however, one arrangement which I think would be better than this, and that is to have two projections made inside the ordinary circular openings in which the rods, &c., work (fig. 3); this would be practically the same as the triangle, but would be better in many ways: the projections might be made very small.

The advantages which would be found by adopting the plan above suggested would be that the various parts of the "rest" would be much firmer when screwed up than is commonly the case now; a much lighter pressure of the screw would also suffice, and hence the annoyance of finding screws tight "set" would be less likely to occur; lastly, by this plan, the rods could be made looser in the holes without loss of steadiness, hence greater freedom of movement when the screw is withdrawn.

SUCCESS IN CARBON PRINTING.—THE OTHER SIDE.

THERE can scarcely be a doubt that carbon printing is the question of the day amongst photographers. The complaints of some, as much as the enthusiasm of others, are evidence of this fact. And it is clearly the duty of representative journals to give effect to every phase of the discussion of this question. In a recent article we remarked that tuition, either written or oral, was an indispensable preliminary to success; and there can be little doubt that in a new art of a manipular kind, personal lessons are of primary importance. But, after the best aid of that kind has been secured, there can be little doubt that very much must remain to be mastered by experience, and by passing through those failures which are proverbially the stepping-stones to success. It has been the legitimate boast of photography that the hearty and willing inter-communication of experiences amongst its devotees has been the chief agency in its rapid progress. And we need feel no hesitation in expressing our satisfaction that these pages—those of the first weekly journal devoted to photography—have contributed materially in facilitating such easy and rapid inter-communication of failure and remedy, difficulty and solution of the difficulty, upon which so much of success depends. That every legitimate complaint should have its expression, we regard as one of the primary canons of journalism, especially in technical journalism. And that, in the main, complaints are based upon a real difficulty or grievance, to be met with the best aid and information available, and not pooh-poohed as the outcome of incapacity or impatience, has been with us a settled conviction. Happily we have had the good fortune, as a rule, to be associated with a staff of contributors, and an army of correspondents, who have, in relation to the various processes, aided us in making plain a path through all kinds of technical troubles, and we have especial satisfaction in pointing in our present and recent numbers to articles dealing with the prominent difficulties of carbon printing, and furnishing that ounce of help which is proverbially better than a pound of advice. And we are happy to add that, in the majority of instances, we are furnished with examples of the successful working of our correspondents. Mr. A. Wellesley Turner, whose interesting communication appears on another page, sends us some admirable specimens in the form of cabinet portraits.

The recognition of the importance of carbon which found expression in the recent discussion at the Society naturally excited hope amongst the legion of workers eagerly anxious for hints; but, unfortunately, the dis-

cussion did not issue in much practical information; and many correspondents have written complaining that it resulted in much confident affirmation, but in little more. And some correspondents protest against the implications of incapacity amongst photographers as the chief causes of failure. One angry correspondent writes:—"When Mr. Jabez Hughes speaks of failure being more the result of bad manipulation than bad tissue, he may fairly be credited as speaking for himself; but he has no right to fling such a charge against the hundreds of capable men who have for years struggled with the process." To this correspondent, and others expressing similar views, we may remark that Mr. Hughes said he spoke for himself, and we may call their attention that he also said he spoke these things for consolation to others who were struggling. And surely it should be a consolation and encouragement to know that the experience gained in struggle will end in success. Encouraging words are certainly valuable. Baily, the author of "Festus," has well said, "Men may o'erget delusion, not despair." It is important, on the other hand, to know that there are real difficulties to be overcome in working carbon successfully, and that the most successful still meet those difficulties, but meet them with fresh effort. "If your sword is too short, add a step to it," was the advice given to the Spartan youth. Good carbon work is worth effort, and photographers may be assured that the process must come into general use. Our remarks at present are chiefly introductory to some observations by a gentleman of our staff, who has had many years' experience in connection with carbon printing, who feels it important to speak his mind on the subject at the present moment, on both sides of the question. We need not comment upon his remarks, beyond observing that the practical history of carbon printing began with the publication of Swan's process, and is really much shorter than he assumes. And we may add that to us it seems that to an entire novice carbon printing would not present more, probably less, difficulty after the first lesson than silver printing. Our contributor shall now speak for himself:—

"In the discussions upon carbon printing at the last meeting of the Photographic Society, as in the case of most deliberations upon the subject that have lately taken place, two points were boldly advanced, and were apparently undisputed. The first is, that whatever failures carbon printers may experience, it is never the material that is at fault; and, secondly, that printing in permanent pigments is, in point of difficulty, no worse than the albumenized paper process, which was just as long in coming to maturity. These assertions have been so often repeated that they will one of these days be taken for axioms, and, for fear such should be the case, I think it worth while to utter a feeble protest against any such absurdities. To come to matters of history, it may safely be asserted that printing with bichromate has been known quite as long as, nay, longer than, printing upon albumenized paper. No doubt, while Poitevin, Fargier, and others were occupied in their first attempts at printing with the help of pigments mixed with gelatine, albumenized paper was rapidly coming into general use; and while Laborde, Blair, and Swan were still struggling to produce satisfactory impressions in carbon, albumenized paper had long since attained perfection. But what does this prove? Simply, that the albumenized paper process is a far simpler method than carbon. 'Consider for a moment how long it was before albumenized paper came to perfection,' say the advocates of carbon; 'remember the long years that elapsed before we secured a tone to our satisfaction, and a surface free from reproach.' All this is very well, but I cannot admit that it proves anything. As I say, printing with bichromate was known before albumenized paper, and if one process was not more difficult than another, how is it that printing by the aid of gelatine has been so long in abeyance? It was certainly not for want of workers. The most intelligent

and learned experimenters have taken part in the elaboration of the carbon process, and if it had not been so we should not be where we are at the present moment. But, after all, have we really been all these years bringing the albumenized process to its present state of perfection? I trow not. On the contrary, I could name well nigh a score of photographers who protest that the albumenized prints of twelve or fifteen years ago are better than those produced to-day—that they are more permanent, and of a better tone. What has been done of late has not been to improve the albumenized paper process, but to rather injure it. The complaints which have been published in these columns fully testify to this fact, and photographers, as they know very well, must use a good deal of discretion now-a-days in the purchase of their albumenized paper, especially if they go to a foreign market for their wares. No, the albumenized paper process has not been all these years coming to perfection; it was known but a very short time before the difficulties connected with it were got over, and photographers, I assert, who print to-day upon albumenized paper are no better off than they were fifteen years ago. If, on the other hand, it is not the albumenized paper, but the manipulations connected with it, that are meant by those who say that one process has quite as many difficulties connected with it as the other, then I join issue again. Give a man, totally ignorant of photography, a negative, together with a sheet of albumenized paper, and some tissue, with a memorandum pinned to each describing the various manipulations, and ask him to produce a print as soon as possible by both processes. Can any one doubt for a moment that he would secure a better picture with the albumenized paper than with the carbon tissue? A novice, as everybody knows, after a few simple instructions, is in a position to produce a whole batch of albumenized prints—carte-de-visite portraits, or landscapes. Would he, however, be able to do such a thing with carbon, having the same amount of instruction? Why, we are told by men who have been photographers all their lives, that they have been to the fountain-head for instruction, and yet they fail in producing good carbon pictures continuously. Again, as to the first point, the immaculate character of the materials with which carbon printers are supplied. Is it so very certain, after all, that these cannot be improved upon, and that they must inevitably produce pictures if only properly handled? This is not my opinion, at any rate, however it may satisfy others. To my thinking, there is a great deal yet to be done in improving carbon tissue and transfer paper, and it is surprising to me how clever photographers—who have conscientiously worked at printing in permanent pigments, not for a month or two, but for years—can tacitly sit by and be told that, whatever may be the cause of their failures, the materials with which they work must be exonerated from all blame. It is permitted to criticise the quality of albumenized paper. Why, then, should the materials connected with carbon be declared sacred and *sans reproche*? My experience of carbon printing—and I say so without the slightest reserve—has taught me that there is good tissue and bad tissue, good transfer paper and bad transfer paper; and I should as soon think of believing in the universal excellence of carbon materials as in my own fitness always to produce good photographs. And now, having said so much, and reminded my brethren that there is another occupant of the stable as fit to carry a saddle as themselves, let me bear every testimony to the good faith and perseverance of the gentlemen of the Autotype Company, and of all those who have made the tissue what it is. If the materials that are produced are, as I have said, not immaculate, they are, I fully believe, as good and as uniform in quality as it is possible to produce them. Let photographers try and try again, for it has been demonstrated over and over again that the finest work and the most delicate of productions, which are permanent to a degree, may be prepared

from the materials as they are now to be had in commerce. The Autotype Company has worked hard and perseveringly for many years; it has called in the aid of scientific and technical men of great experience, and the stage of perfection that has now been reached is but a just reward for their enterprise. I exhort photographers throughout the length and breadth of the land to engage in carbon printing, and if they do not succeed at first, it is five chances out of six that it is their own inexperience, and little else, that is at fault. At the same time I repeat that it is quite possible faults may lie in the materials themselves, and herein may chance to be the source of their troubles. The carbon process is a difficult method of printing at best, and carbon materials are also difficult of preparation. We are rapidly improving both in the one and the other, but we have not yet arrived at perfection in either respect. Carbon pictures are now produced quite as charming in every particular as silver prints, and every day, too, in large quantities. But it were idle to deny that it is not a process requiring particular care and skill in all its details, if pictures of uniform excellence are to be obtained with it.

RAPID EXPOSURES.

THE *Arctic* publishes a communication from Mr. Conrad Petersen, now resident at Fayeth County, Texas, in reference to rapid exposures.

A silver bath to sensitize plates, requiring but a third the usual exposure, may be prepared, says Mr. Petersen, as under:

Nitrate of silver	8 ounces
Iodide of potassium	40 grains
Nitrate of baryta	288 "
Pure distilled water	96 ounces

The bath is filtered, and a little nitric acid is added to make it work clear.

The collodion employed is made from "Anthony's snowy cotton" washed in water containing a few drops of ammonia; it is rinsed afterwards in pure water, pressed in a cloth, and allowed to dry in the sun, so that no trace of ammonia remains behind. To each ounce of ether and alcohol mixture I take five grains of this pyroxiline.

The iodizing solution for an ounce of normal collodion is prepared of:

Iodide of ammonium	3 grains
Bromide of cadmium	1½ "
Iodide of cadmium	2 "
Bromide of potassium	1½ "

These salts are rubbed down in a dry mortar and dissolved in alcohol. The developer is composed of:

Double sulphate of iron ammonium	3½ ounces
White sugar	420 grains
Glacial acetic acid	1½ "
Rain water	10 ounces

Before use there is mixed with every three ounces of this developer twelve ounces of rain water and one ounce glacial acetic acid.

CARBON PRINTING.

BY A. WELLESLEY TURNER.

THIS subject cannot but be of great interest to the profession, and although so much has been written and said on the subject that, to the few, if any, who take no interest in a matter so important, the very title of my article would be voted a bore, still there seems to be a want of knowledge among many photographers of the progress carbon printing has been making, and more particularly why it has not advanced in greater strides. The constant mention of this subject in the journals, and the anxiety for information shown by the profession, proved

beyond doubt that the craving for a permanent process of printing is still as great as ever; and yet the general tone of the speakers at the meeting of the British Photographic Society, held specially for the consideration of this subject, seemed in my opinion to lack that character that should mark a really commercial process. If, then, this method of photographic printing is so perfect as we are so often told, and the interest in it so great, how is it that it is not more generally used? This question must necessarily suggest itself to every thinking photographer who has not yet commenced working it, and consequently throw some doubt on its genuineness. We all know that to make anything popular requires two classes of workers. The first must be energetic and scientific men, to clear and pave the way to the desired end; and when this object is attained, it is only natural that the second class will follow and share the advantages gained by the first, it being their share of the labour to make the process more popular and general. Of the former class I consider we have had our full share giving their time and skill, as well as expending vast sums on carbon printing; but to bring it before the public, it is the second class of men that is required. Why this is so, then, is the object of my present article, and I consider I have studied the process under circumstances that give me special experience to speak on this particular branch of the subject.

Many, I feel fully aware, will say that the progress has been great in carbon printing, and that all good things, before they take a strong hold on the public, require a long time to properly mature. In answer to this I feel justified in saying, that seeing the lack of information on this subject disclosed to any casual reader of the journals, carbon printing has not made anything like the progress it should have done; and, in the second place, that it has had a very long probation, and been brought before the profession more often and with much greater inducements than any other process in photography. For years we have had it placed most temptingly before us, and yet how few have adopted it as a commercial thing! Many, on the other hand, may say that there must be some insurmountable difficulty in the process that renders it thoroughly uncommercial. To these I can give a plain unvarnished negative: I have been working the carbon process four or five years, at first principally in large work, but latterly for carte and cabinet work, and as I think there can be no doubt as to the suitability of carbon for large work, I will now confine my remarks to the latter branch. For over twelve months I have paid almost exclusive attention to the enamelled prints often called chromotypes, and during that time, winter and summer, I can honestly say that I have met with no absolute difficulty that any skilled printer might not easily overcome.

I will not go so far as to say that this process is cheaper and easier than silver printing, as I feel sure that no one who has practised it can, without prejudice, affirm; in fact, I believe that to exaggerated statements of this class we owe much of the failure we have heard of, and this, together with the fact that carbon printing has such a strong antagonist as silver printing to fight against, is what will best answer the question, Why has not carbon printing made greater strides? Those writers who so triumphantly proclaimed the great advent of carbon to the extermination of silver did not reckon the power of the foe they so assuredly prophesied the overthrow of, for had they a moment considered the qualities of the two processes side by side, as I purpose doing, they would have come to the conclusion that silver printing has too many advantages in the balance for carbon printing, even with the weighty advantage of permanence, to turn the scale in its favour. This is the greatest stumbling-block to carbon, viz., that silver printing so nearly fulfils all the qualities required by the photographer, even with permanence, to a great degree, if carefully worked; and from this fact I maintain that it

is not any physical defect in the process that has retarded the progress of an otherwise invaluable method of printing.

Let us now, without prejudice, consider the two parties face to face, and see which presents the most favourable aspect by the comparison to the generality of the photographic profession.

Taking a perfect silver print on ordinary albumenized paper, and an equally good enamelled carbon, I think the weight of qualities, as far as artistic appearance goes, would be equally divided; some, I am aware, prefer the splendid surface of the carbon, whilst others would consider the plain albumenized print more artistic. But as opinion on this subject is so various, I think we might give equal palm to each; both carbon and silver bring out the delicate detail of the negative to a wonderful perfection, although in the case of some class of negatives I would give preference to the former process; and I am of opinion, also, that the enamelling of the carbon print brings up the deep shadows with more brilliancy; but we must remember that silver prints can also be enamelled, although so seldom done, and, therefore, any qualities brought up in the carbon by this means should not be allowed much weight. So far, then, as mere appearances go, we must leave to individual judgment and public taste.

We next come to the physical qualities of both processes, and in this respect I think we can safely give the verdict in favour of carbon. It is undoubtedly permanent if fugitive colours are not used in the preparation of the tissue, whilst we all know that the longest life we can guarantee to the most carefully-worked silver print is not more than fifteen or twenty years. This is the most important, and, I may say, only point entirely in favour of carbon, and the one that will ultimately turn the balance, if anything will. As there can be no doubt on this branch of the question, I think it unnecessary to say more.

We now come to the plea most in favour of silver, viz., ease and cheapness of production. Without going into actual figures, I can say, from a considerable experience on both sides, that silver printing is much cheaper, reckoning the actual cost of production, by a long way, and requires less labour of a skilled character to produce. As far as certainty of results go, this at present is in favour, also, of silver; but this is caused principally by a want of more experienced printers in the new process, as many workers have affirmed. I have no doubt that when carbon printing is more generally worked, it will produce an equal quantity of good results, at, of course, greater outlay in materials and labour; but this difficulty can be overcome by charging a higher price for the production, in which direction at present there is plenty of room in photography. We can now see how it is that the older process still retains its place in the studios of most photographers. How tempting it is, when a young beginner in carbon finds things working wrong, wasting both time and materials, as well as temper, over one process, whilst another method is within call that he has been using for years, and with which he is so well acquainted, knowing at the same time that it pays better, and pleases his patrons for the time, at least, as well! Why, then, he argues, should he trouble himself? and so he either puts it aside till a more fitting time, which may be long in coming, or discards the process entirely, and begins, like the fox and the grapes, to persuade himself that silver printing is quite permanent enough. This, it may be remarked, is rather a blue look-out for the new comer. What are we to do with carbon printing? Are we to discard it entirely for small work, or to practise it at a loss? Certainly not, I would say; it is too good and practicable for the first fate, and it would be absurd to think of working it on the second condition; besides this, it is a thing both photographers and the public require.

We have long been striving after a process with beauty and permanence combined, and here it is, though still, for

the reasons I have stated, not received with the welcome it deserves. What is required, then, is that the profession should properly understand how carbon stands, or, if I may use the expression, its social position in the society of processes. This has been my object in the present article more than technical information, which any photographer may easily obtain either by visiting the Autotype Company, or by obtaining its Manual, and for himself practising the process first on a small scale till he has thoroughly mastered its difficulties, and afterwards commercially. If every photographer would do this—and it would cost but little to begin with—we should see carbon prints in every studio, and consequently the public would become acquainted with the process, and better able to understand its qualities; it would be more prominently brought before their attention, and chromotypes or carbons would become as much a household word and necessity as cartes and cabinets are now. As it is at present, the public only see a few here and there distributed over the country, and look upon them as of no importance. I have myself heard many of our patrons remark, when they are introduced to their notice, something to this effect: "Oh, yes; they are those glazed things they are so fond of on the Continent!" and they evidently imagine that they are only the ordinary style of things enamelled or varnished up. Of course you remind them of their permanence, but this, in nine cases out of ten, they have been told a dozen times before of other processes which they have gazed on, till they gradually lose their bloom, and consequently they only place such remarks in the same category that they would if any tradesman told them that his particular wares were so much better than those kept by the gentleman on the other side of the street. They therefore often shrug their shoulders, and pay very little attention to the boasted permanence, as it cannot be proved on the spot. If, on the other hand, every photographer had permanent photographs in his studio, the public would see that the profession had more confidence in the process, and think that the thing was therefore more genuine; and this is what we really require to make the process the thorough success it deserves.

After advocating the more general use of carbon, it would only be right for me to offer to give any assistance I can in the technical difficulties of the process, which I shall be happy to do at a future time.

(To be continued.)

CARBON PRINTING.

BY GEORGE CROUGHTON.

DOUBTLESS many besides myself have been disappointed at the result of the discussion upon carbon printing, for it cannot be disputed that although there has been a deal of talk, there has been little or no practical information upon the subject.

The discussion at the Photographic Society of Great Britain was both satisfactory and unsatisfactory. It is eminently satisfactory to hear that Mr. Hughes has returned to carbon printing after deserting it, but it is very unsatisfactory not to know the cause of such desertion. It is interesting to know that Mr. Hughes' temporary return to silver printing has only tended to disgust him with it, but it would have been more interesting and instructive to have heard what were the troubles which forced him to such temporary return to silver printing. It could have been no slight trouble which would cause such an indefatigable worker as Mr. Hughes to give up carbon even for a short time, after telling the photographic world that he had banished silver printing altogether from his studio, and which sent him to the four corners of Great Britain in search of information upon the subject; and it would no doubt have been worth a great deal to have known the evil, and its remedy. But of course Mr. Hughes has a perfect right to keep the know-

ledge acquired at the expense of so much time and trouble, and he must have regarded the discussion meeting somewhat in the light of a trap to catch information. Mr. Fry, who opened the discussion, left the subject much in the same position as when he took it up, and for practical information you may almost say the same for all the speakers except Mr. Sawyer, who gave a most valuable explanation of that bugbear of carbon printers—reticulation: this alone would be sufficient to redeem the discussion from utter failure as far as practical details are concerned. Nor has the discussion in the pages of the *News* fared much better. We have had an experimentalist asking for information, and getting a setting down by a successful worker. Now although, to a certain extent, a successful worker also, and, like him, a licensee of the Autotype Company, I have, like "Experimentalist," been looking for some of the great successful workers—those who have been so successful as to be able to banish silver printing altogether—to give us their experience, that we might all know the secret of their great success; but, alas! the time for free interchange of thought and experience is over; every one holds fast what he gets, and "Experimentalist" has to ask in vain; so for want of a better, and in the hope that my experience and difficulties may tempt others better qualified to speak, I will just step into the gap, premising that on and off I have worked carbon for the last seven years for large work, and as a basis for colouring, &c., but only of late have I tried it for small work, such as carte or cabinet portraits, and although successful to a certain extent as an experimentalist, I cannot boast of being so successful as to be able to banish silver printing, or even to put it in the least aside for the usual carte or cabinet work. But, as I believe the days of silver printing are numbered, and that it is sound policy to keep pace with the times, I think it is well to be ready for the change when it does come. There is always the satisfaction of knowing that carbon prints will repay the trouble of their production in respect to their permanency.

"A Successful Worker" says that "Experimentalist," and all like him, should go to the Company and pay their fees like men, and get proper instruction. Just so say I; for there is nothing like seeing a thing done, for far more can be learned by one hour's personal instruction than by twenty hours' reading. But it is one thing to see a clever manipulator go through all the various processes, with materials in proper condition, and every appliance in perfect order; and quite another to come home and try to do the same thing off hand. You are totally unacquainted with your materials, you omit some little detail to which you attached no importance, and then in step the troubles, and hints from successful workers are desired. I have found the Autotype Company always ready and willing to answer enquiries as to difficulties, &c.; but in the hope of assisting some beginner, and of inducing some successful worker to follow, I will give my experience without further preface.

Well do I remember my first trouble with the tissue. I was using the double transfer process, developing upon grained zinc plates. This one simple thing caused me great trouble and anxiety. We were just giving up silver for carbon as a basis for coloured and finished work, and several evenings before leaving the studio I had hung up to dry some six or eight sheets of various sizes for use in the morning; but time after time they were found perfectly useless, being quite insoluble in the hottest water. After this had happened four or five times, I took some of the much-abused tissue home with me, and sensitized and dried it at home, bringing it to the studio with me in the morning. This worked all right, so I made strict enquiries among the boys, and found that the first thing in the morning the printer's assistant, whose duty it was to wash out the dish and put the silver to filter, did this with the *dark room window open*, and as my pieces of carbon were hanging just in front of it there was a sufficient explanation of its insolubility. My next trouble arose out of this incident.

I cautioned the lad not to have the window open, and explained to him that the pieces of patent leather were more sensitive to light than sensitized albumenized paper. The next morning, when I went to take down my carbon, I found my paper hanging, but the carbon was upon the floor. The lad, thinking to get the stuff out of the way, had lighted the stove as soon as I had gone, and got up such a heat that the tissue slipped off the paper. These troubles you will say were simple enough, but they arose from the same cause as Mr. Hughes tells us his troubles came from, viz., imperfect acquaintance with the materials.

Coming to later times I can see (in the light thrown upon the subject by Mr. Sawyer) that most of my troubles have had for their cause the hurried drying of the tissue, and in contrast to most carbon workers I have been more troubled in the cold weather than in the hot, and this is easily explained. In the summer I have allowed the tissue to dry spontaneously, and success followed; in the cold weather heat was used, and I overdid it, and dried too quickly, causing reticulation and granulation. Another cause of reticulation will be found, I think, in too short an immersion in the cold water before putting down upon the support. This will not show if the tissue is developed upon paper direct by the single transfer process, or upon the temporary support; but it will at once upon the collodion. It can be explained, I think, in this way: by putting the tissue upon a rigid surface before it has expanded as much as it will, the reticulation is caused by its expansion after being attached to its rigid support; but for the sake of young experimentalists I will go over each detail of the manipulations separately, knowing that the importance of the subject will be sufficient excuse if I repeat what has been written before.

(To be Continued.)

THE AMERICAN COMPETITIVE EXHIBITION OF PERMANENT PHOTOGRAPHS PRODUCED BY THE CARBON AND LAMBERTYPE PROCESSES.

THE above competitive exhibition, of which comparatively short notice had been given, took place on the 11th of January.

There were fifty exhibitors from various parts of the United States and Canada, and some pictures made by European artists were also shown. Col. Stuart Wortley had sent some from England, but although they had arrived in this port, they could not be got through the Custom House in time to be placed on exhibition. M. Liebert, of Paris, had proposed to send his Centennial display, but in consequence of the high charge for U.S. duties they were returned to France. The whole number of productions by the various processes was three hundred and fifty-five, and it may be fairly said that there were none that were not equally as good as silver prints could have been made by the same persons, while the larger quantity were far superior, in our opinion, to any that could be made by silver from the same negatives.

We were quite pleased, if not surprised, by the large number of exhibitors and the prevailing excellence of the work. Besides the exhibits for which medals have been awarded—and several arrived too late for competition—were some very excellent productions by the Lambertype processes from Messrs. Dimmers, of New York; Wykes, Quincy, Ill.; Wallin, Fort Wayne, Ind.; Milnes, Hamilton, Can.; Vail, Geneva, N.Y.; Poole, St. Catherine's, Can.; Saunders, Alfred Center, N.Y.; Allen, Pottsville, Pa.; Potter, Warren, O.; Klauber, Louisville, Ky.; Brooks, Dundee, Can.; Smith, St. Alban's, Vt.; Roth, New Orleans, La.; Higgins, Bath, Me.; Sherman, Elgin, Ill.; Ross, Syracuse, N.Y.; Holton, of Boston, Mass., and others.

The gentlemen who kindly acted as judges, and who are all proficient in photography, have unanimously testified to the practical excellence of the modes of working.—*Anthony's Bulletin.*

Correspondence

NOTES ON CARBON.

SIR,—Mr. Jo. Vestris' letter under the above heading is quite to the point, and he says exactly what I should always have refrained from expressing, not wishing to incur uncharitable rebukes which might have been to the effect that interested motives prompted me in making the suggestions, because I happen to have secured exclusive rights for several other towns besides my own, and wished to dispose of the licenses. I would not occupy your space even now, were it not that I am in a position to answer the question "How are we to help the photographers of Edinburgh?" They require no help at all in the matter; if they wish to help themselves, they have only to call upon Mr. Ayton, who is quite willing to dispose of sub-licenses to them at the ordinary price. This being correct information received from Mr. Ayton himself, I think it will show that the want or absence of improvement in that direction is not due to the selfishness of any member of the profession who has been enterprising enough to lead the way.

As it is very desirable that no misconception should exist on this point, I may be permitted to remark that I am placed in the same position. I have never refused to treat with other members of the profession on what it is agreed to consider "equitable terms"; but I must say that very little desire has been shown to adopt the processes of Mons. Lambert, even after it has been satisfactorily shown that they are workable, and can be made to produce superior results. To what cause or influence this may be attributed I care not to enquire. Suffice it to state that many problems had to be solved by the licensees after they were left to themselves, and it is gratifying to know that in the face of many drawbacks complete success has been achieved in many quarters.

One word more, and "I expire," as our trans-Atlantic friends say in their "real live journals." From the first a sort of tacit fraternal understanding has existed among the chromotypers, and the more successful ones have never refused information and assistance of every kind to those who applied for any. It has often been given at considerable personal trouble, and received very few thanks; but that need not surprise any one who has lived long enough in this world.—Truly yours, C. FERRANTI.

THE PHOTOGRAPHIC SOCIETY CARBON DISCUSSION.—"PICKING UP" THE PROCESS.

SIR,—The so-called carbon discussion seemed to be "much cry and little wool." All that took part in it sang a psalm of praise to its glory; but for real practical hints there were none. True, Mr. J. Hughes hinted at difficulties—great ones—but did not explain what they were, or how he overcame them. This is not like the Mr. Hughes of old, who ran a difficulty to earth, and then told us all about it. Now, I have "picked up" the carbon process, and am desirous of issuing all my work by it; but I do not feel justified in advertising to do so with the possibility of, perhaps, bye-and-bye being brought to a dead lock. Mr. Hughes and others may say—and, in fact, do practically say—"We paid for our learning: you do the same." I venture to hint, with all due deference to those gentlemen, that it is not the spirit of the photographers of old, nor in the spirit that has made photography what it is; and it must have a tendency to retard progress in what all of them are professing to desire, namely, permanent photography.

Now, as to "picking up" the carbon process, we all know that the Lambertype is a patented process, and we must pay a fee for its use, and I think it is generally acknowledged that it is quite a justifiable patent, and a reasonable fee; but, on the other hand, the Autotype Company are urging photographers to print in carbon, and the ordinary double and single transfer is quite free to all that choose to use it. I advise intending Lambertype licensees to learn and

perfect themselves in the ordinary process before going in for the other.

If those anxious to learn will purchase the last edition of the "Autotype Manual," and carefully follow instructions, they will be able to produce carbon prints by the ordinary double transfer quite equal to silver. It is recommended to finish by polishing with the waxing compound. I use plain collodion after the prints are spotted, rolled, &c., and, when dry, roll again. There are no special dishes required unless you like, and the Autotype Company supply them if wanted. Neither are special printing frames required (see a hint by Mr. G. Croughton in *YEAR-BOOK*, page 89, on that subject); but do not use albumenized paper for transfer—it will fade. The Company will supply the tissue in small or large quantities ready sensitized. Photo-purple is good. Auto-brown I prefer for small work. You can also get very good transparencies for enlarging by using the engraving-black; coating a plate with collodion, washing it, and, while still wet, developing your picture on it. If not deep enough, dye it with Judson's dyes. Crimson-lake I find answer, giving a nice bloom to the transparency. By getting the tissue ready sensitive you escape one of the greatest troubles. Do not buy too much at once, as after a time it becomes insoluble. Do not be in a hurry, and do not suppose you are going to succeed to perfection the first time of trying because you "know all about photography, you know." Go about it in a proper way, and you will like it. It is a charming process, and quite a change from hum-drum silver. Trusting these few hints will be useful, and that all anxious to learn will try carbon, and give us some of their experience in return, I am yours, &c.,

ONE THAT HAS PICKED IT UP.

FADED LIGHTDRUCK PRINTS.

DEAR SIR,—My attention was directed at a very early stage of my work to the fading of prints produced in the press. It was my custom to use the best colours, such as are employed in fine litho work, but to my horror I found that an exposure to sunlight of even a few hours was sufficient to perceptibly change the colour of the print, whilst a few days' exposure to ordinary daylight was sufficient to eliminate almost every trace of colour, leaving, of course, the black unchanged.

After much trouble, and a good deal of hard work, I at last succeeded in preparing pigments which would work kindly on the press, give all the transparency that the lakes afford, and be of an absolutely permanent character.

Still it is just the same with this as with the pigmented gelatine, a picture in either of them cannot be permanent if fugitive pigments enter into the composition.

May I beg you to accept a few prints? They are part of a series of 800 plates for a great work *Les Travaux publics de France*, now being published by M. Rothschild by authority of one of the Ministers of State; and it says something for the progress of the art in England, that we should have been able to compete successfully for the production of this work, against the many able workers on the Continent.

The proofs are from reproduced negatives, are on toned thin paper, and are sent in this state to be mounted with handsome border and title in Paris.—Believe me yours very truly,

J. R. SAWYER.

Ealing Dene, Feb. 7th.

[The prints enclosed are excellent, and practically indistinguishable from good silver prints on albumenized paper.—ED.]

Proceedings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE monthly meeting of the South London Photographic Society was held in the Society of Arts Rooms, on the 1st inst., Rev. F. F. STATHAM, M.A., F.R.S., President, in the chair.

After the reading of the minutes of the previous meeting, Messrs. A. Harman and Bolas were elected members.

Mr. WILLIAM BROOKS then read a paper "On Transparencies by the Emulsion Process" (see page 61), and submitted a number of pictures for exhibition.

The CHAIRMAN, in thanking Mr. Brooks for his paper, contrasted his generosity in publishing so freely the details of his process with the reticence of others who had experimented with emulsions.

Mr. J. T. TAYLOR could scarcely agree with the Chairman; for, in his estimation, experimentalists in the collodion emulsion process had very freely given to the world the results of their investigations. He considered that the decline of stereoscopic photography was more owing to the want of a convenient form of stereoscope than, as attributed by Mr. Brooks, to deficiencies in stereoscopic slides.

M. LEON WARMERKE found that a variety of tones in an emulsion picture could be produced by giving it a long or short exposure. A long exposure usually gave warm tones.

Mr. SPENCER said that in point of expedition in producing a transparency for use in enlarging the emulsion process certainly possessed advantages over the carbon process.

Mr. TAYLOR having observed that by giving an edging of tallow to an emulsion plate the necessity for a substratum of albumen was done away with,

Mr. MAWDSLEY said that this application of tallow to the margin of the surface proved highly beneficial, and he could strongly recommend it.

Mr. NESBITT exhibited a number of transparencies taken by collodion emulsion prepared by himself. He observed that the process was a very fascinating one. In making emulsion he preferred a slight excess of bromide.

Mr. HENRY had been very successful with emulsion work, and trusted that the numerous fine specimens that had been exhibited that evening would prove an incentive to others to try the process.

Mr. FRANK HOWARD was gratified to find that the difficult question of obtaining a pleasing tone had been so successfully met by Mr. Brooks.

Mr. YORK did not consider it possible to obtain such a good tone by means of camera printing as by superposition, nor did he see that any advantage was to be gained, in respect of rapidity, by adopting the method advocated by Mr. Brooks.

A conversational discussion here ensued on the effects produced on the tone of the transparency by the duration or shortening of the exposure in the camera, in which Mr. Foxlee, Mr. Beasley, and others took part.

Mr. BROOKS having replied, a number of transparencies were exhibited by the magic lantern, after which the meeting separated.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

THE Board of Management held their monthly meeting at the Offices, 174, Fleet Street, on Thursday evening, February 1st.

After the dispatch of the ordinary routine business, Mr. E. Lavender was admitted a member of the Association.

The Sub-Committee then presented a petition for assistance which they had thoroughly investigated, recommending it as a most needy case. Upon motion, the sum of £5 was voted to relieve immediate distress, and steps taken to procure employment for applicant.

Some of the members then dwelt on the desirability of making better known the advantages of the Association to its members (members' applications for assistance only being entertained); the subscriptions being fixed at such a rate that all persons engaged in the various branches of photography are enabled to support it.

There being no further business, the meeting adjourned till Thursday, March 1st, at 8 p.m.

Talk in the Studio.

SEAVEY'S BACKGROUNDS.—Mr. J. J. Atkinson, of Manchester Street, Liverpool, writes to us as follows:—"In the PHOTOGRAPHIC NEWS, February 2nd, I see, in reply to correspondent 'W. W. W.,' you speak of Mr. Seavey as a professional background producer, living in New York; and you refer to the need of good background artists, generally, in connection with photography. Holding this view myself, and having a very

favourable account of Seavey's work, I sent an order to him for a sample of half a dozen of his best backgrounds, and have just received them." Photographers generally are familiar with Mr. Atkinson's enterprise in connection with American photographic specialties, and many will be glad to learn that they may obtain the backgrounds in question. Communication direct with Mr. Atkinson will, doubtless, bring all the detailed information required.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The Annual Meeting of this Society will be held on Tuesday next, February 13th, at 5A, Pall Mall East, when the Report of the Council, and other business, including the election of officers, will be transacted; after which Mr. H. Baden Pritchard, F.C.S., will read a paper on "Photography from a Holiday-Maker's Point of View."

THE SEA INVADING STUDIOS.—A correspondent at Blackpool says:—"It seldom happens that photographers suffer from the inroads of the sea. Hence, it may interest some of your readers to have recorded some of the doings of Neptune at Blackpool. On Tuesday last the place was visited by a strong S.W. gale, which brought a heavy sea over the promenade, causing a great destruction of property. Photographers came in for their share of damage. At the extreme north Messrs. Wolstenholme's studio was slightly injured; going south, Mr. Wright's studio had the roof blown off, the lights broken, an end blown down—indeed, almost wrecked. Mr. Ward comes next, the studio floor being damaged, and about thirty feet of a nine-inch wall knocked down. Mr. G. S. Haigh follows, the sea making a clean breach through, breaking in the shop front, and sweeping the full length of the studio. The wooden studio of Mr. Isaac Wilde was entirely wrecked—not a particle left standing. Mr. Harrison's studio (yet farther south) was seriously injured, the front broken in, and the sea rushing through. The loss must be very serious, and is a matter for regret." A disaster even more serious occurred a few weeks ago at Margate, as we learn from a letter in the *Daily Telegraph*. The writer says:—"Amongst the many thousands of visitors who throng the cliffs of Margate during the season I doubt if there is one who is unfamiliar with 'Bijou.' His photographic studio stands within a stone's throw of the Cliftonville Hotel, and for many years has been adorned with spirited sketches of no ordinary talent. But storms and tempests have no regard for art, and on the first day of the new year 'Bijou's' studio was destroyed by a sudden gust of wind. Certainly the damage done in this case is very small compared with the severe losses in other parts of the country, but it must be remembered that this studio represented the only means 'Bijou' possessed of providing for a wife and several young children, and now this is gone he has made an appeal to the public to help him to repair his loss. May I ask you to give publicity to this case, as I feel sure your readers would gladly send a trifle to make up the small sum needed (I imagine less than £100 is required) to re-instate 'Bijou' in his studio. From an advertisement that has recently appeared, I observe that donations will be received at the Margate Bank; but if any visitor to this town feels able only to contribute a sum too small to send to a bank, it will be gratefully acknowledged if addressed to me at Dixon's Library, Margate.—I remain, sir, yours truly, D. S. 14."

M. LAMBERT IN AMERICA.—The American journals teem with correspondence on the carbon question. The enthusiastic licensees of M. Lambert are unmeasured in their expressions of praise. The *Philadelphia Photographer* is in antagonism with M. Lambert, and this has stimulated his licensees to much plain speaking. Mr. Theo. Lillianthal, of New Orleans, says:—"Since I became familiar with M. Lambert's processes, I have met with no more failures than by the silver processes, and could, and would willingly, abandon the last if my charges for carbon work were not higher." Many other letters are to a similar effect. The Competitive Exhibition passed off successfully, bringing together a large mass of fine carbon printing.

INTENSE LIGHT FOR TAKING PHOTOGRAPHS.—A very brilliant, perfectly white, and very actinic light, which may be used for taking photographs, is produced as follows:—Place some perfectly dry, powdered nitre in a suitable clay vessel, and in a cavity made in the middle of the powder place a piece of phosphorus and ignite it. While it burns, the nitre melts and a quantity of oxygen gas is given off, producing an intense light.—*Scientific American*.

To Correspondents.

CONSTANT READER.—The fault in the lower part of your portraits, imperfect illumination and imperfect definition, is due to various causes; but chiefly to the imperfection in the lens, which does not cover sufficiently well, and has not a sufficiently flat field. For standing card-portraits, a lens especially manufactured for such work is desirable to secure the best results. If you use a smaller stop, and take care that the lower part of the figure is better lighted, you may, however, secure better results. A lean-to roof is generally better for a small studio than a span roof; and we should prefer it with a studio ten feet wide.

J. L.—The spots appear, undoubtedly, to be due to metallic particles, which reduce the silver at the point. They are similar to those produced by particles of iron in the paper; but they may proceed from other causes; such, for instance, as particles of metallic dust coming in contact with the paper. Such dust may arise from various causes; such, for instance, as the grinding of the hinges of the back-board of the printing frame, or of a box where the paper is kept. If the fault is not in the paper, extreme cleanliness and care in the room where the paper is kept, or silvered, or dried, will best aid you.

SMOKER.—The best stove which we know for the studio or operating room is George's Gas Calorigen, which gives warmth and fresh air without risk of any injurious products escaping into the room.

A. WELLESLEY TURNER.—Many thanks. The cabinet prints are very fine indeed.

TYRO.—The front lens of a portrait combination may generally be used as a single landscape lens; but such a lens is not suitable for the back lens of the combination. But you may combine two single lenses, placing each with its convex surface outwards, and a stop between; the amount of separation being determined by experiment. You can scarcely hope, however, for a very good result, as the combining of lenses of suitable form and focus, to produce the best results, requires all the skill of an experienced optician. The position of the stop is fixed by the respective focus of each lens. If the lenses were of equal foci, the stop should be placed exactly midway between the two. If one of the lenses have a focus of twelve inches, and the other of eight inches, the stop should be placed two-thirds of the distance from the first, and, of course, one-third from the second. If the best results in combining lenses could be defined by a simple formula, the duty of the optician, and success in its application, would be more simple and common than it is.

HASSAN.—So far as our memory serves us, a good series of Egyptian views was published by Frith. A very fine series was produced by Francis Bedford, and more recently by Frank Good. The latter are, we believe, published by Mansell, of Percy Street, Rathbone Place.

J. ROBINSON (Salford).—We do not remember that we have seen any of the enlargements you mention, and cannot offer any opinion, therefore, on the value of the formulae.

A BAD MANIPULATOR.—Skill in manipulation can only be gained by practice and care. Your question, "What am I to do if I belong to the condemned class of bad manipulators?" is scarcely one we should be expected to answer. We might answer that you must suffer the penalty of non-success; but we prefer to suggest that if your skill be less, let your effort be greater. As a rule, skilful and successful men are willing to help their less skilful brethren, as the communications in our pages bear witness; but such aid should be asked and received as a favour, not demanded as a right. A tone of angry remonstrance is as unfair as it is impolitic, and is most likely to defeat its aim. Try again, not once, but repeatedly.

SOCIETY OF GREAT BRITAIN.—The annual meeting will be held next Tuesday. Your voting paper must reach the Secretary before the hour of meeting. You can only vote for those nominated. You might have nominated any one you chose: but the time is now past. We can give you no information as to a presentation print. Write to the Secretary.

F. ROW.—We are obliged to you for a sight of M. Kary's specimens. We are familiar with his claims as to the invention of a special system of lighting, which we described some time ago. We shall have something more to say on this subject in our next. We will return the specimens as you desire.

JO. VESTRIS sends us the following impromptu lines upon a photograph, written in church on hearing the clergyman speaking of the "dear ones departed":—

"Tis not when friends are near we prize them,
When we can hear them speak, and sing, and laugh;
But when, for ever to our presence lost,
We fondly gaze upon their photograph."

Several Correspondents in our next.

The Photographic News, February 16, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE PHOTO-CHEMICAL ACTION OF THE EYE.

A CHARMING discovery has recently been made—the result of researches by two German physiologists, in which photographers thus take the keenest interest. It is no less than that the retina of the eye possesses photographic sensitiveness, and that an image can be secured by its means just as readily as can be done by the aid of a camera and a sensitive collodion plate. Every object we look at, that is vividly lighted, impresses itself on our retina exactly in the same way as upon an ordinary sensitized film. The image photographed upon the retina may be secured and fixed like other photographs, and is in every sense of the same character as these. Such a discovery—as the authors of it point out—may lead to the supposition that there may be something, after all, in those stories of which we frequently hear, of images being visible in the eyes of persons after death, of the retina of murdered men, for instance, showing plainly the image of those who slew them; but, as our readers will find, if they have the patience to follow us, there would be, under any circumstances, little chance of such things being brought about. It appears that three months ago M. Boll, who now occupies the chair of physiology at Rome, discovered the remarkable fact that the external layer of the retina possesses in all living animals a purple colour. This purple surface, he found, bleached on exposure to light; but regained its pristine colour in the dark. Like pure iodide of silver, indeed, you could impress an image on it, and if put away in the dark, the image disappeared, and the substance was again ready to receive a second impression. As Professor Bunsen has pointed out, there are many substances besides iodide of silver in which this phenomenon may be observed; but to M. Boll is due the credit of having shown that we in our eyes possess living matter endowed with such powers. This purple, which is appropriately termed *seh-purpur* (see purple), M. Boll affirmed, vanishes for ever immediately after death; but subsequent experiments have shown that this is not the case, but that the delicate photographic film remains sensitive under some conditions four-and-twenty hours after dissolution. And now we leave M. Boll, who has brought to our knowledge the presence of a sensitive photographic tissue in the eye, and proceed to the still more interesting researches of his disciple, M. Kühne. The latter, who is Professor of Physiology at the University of Heidelberg, was at once struck with the marvellous discovery of Boll, and forthwith determined to push the investigation still further; and he it is who, in a communication last month to the *Centralblatt der Medicinischen Wissenschaften*, tells us the astounding news that he has been able to obtain actual photographic images upon the retina, corresponding with objects which had been looked at during life. No wonder some of us, after viewing some bright object, close our eyes and rub them, and for seconds afterwards see the object in our mind so plainly. If it is photographed upon our retina, we need in future feel no surprise on this score. Also, when we have sat through some bright entertainments, or walked through sun-lit streets for an hour or two, it is surely only natural, if the *seh-purpur* of our eyes has been somewhat bleached, and become, so to speak, insensitive, that we feel a relief in going into the shade or darkness in order that the colour in the retina may once more return to its normal condition. The first important results that Kühne obtained were, it appears, to the effect that the colouring matter did not disappear immediately after death; but if kept in a dark room, illumined by the mono-chromatic light of a sodium flame, it could be preserved for four-and-twenty hours. It can, however, only recover its normal condition when attached to the eye, or, in other words, one can only compare its functions with that of iodide of silver so long as the retina is complete and the purple matter remains in position,

a circumstance which was proved in a most conclusive manner by Kühne. An eye was extirpated, and in one part of it the purple retina was lifted. The colour of this flap rapidly bleached; but as soon as the flap was laid down again, so as to be once more in contact with the inner surface of the choroid, a complete restoration of the purple was the consequence. So that the eye carries with it a living substance which has the power of *resensitizing* the photographic film whenever such a process becomes necessary. It is only, Kühne points out, when the eye is exposed for a considerable time to the direct action of a vivid light that any bleaching or fading of the *seh-purpur* is actually perceptible; but when this is the case, there is, as we have said, an actual photograph produced on the retina which can be fixed and preserved. Such a photograph Kühne terms an *optogramme*, and he tells us exactly how he proceeded in order to secure one. It was necessary to have recourse to a long exposure, as may be anticipated, for as we ourselves know very well, under ordinary circumstances, an image ever so deeply impressed upon our retina never remains there many seconds. A rabbit seems to have been the unfortunate object fixed upon; and poor Bunny was made to fix one of its eyes upon an opening in a window-shutter; the aperture was thirty centimetres square, and the lens or eye of the rabbit was at a metre and a half distance. The head of the rabbit was covered with a dark cloth for five minutes, so that the *seh-purpur* might be as sensitive as possible; and then an exposure was given for three minutes, the light not being very bright at the time, however. Only one eye of the animal was employed, and as soon as the three minutes had expired, the head was instantly cut off, and the eye, having been extirpated in a dark room by the aid of yellow light, was opened, and, as soon as possible, plunged into a solution of alum. The second eye was also extirpated and exposed as the living eye had been for a similar period to the same object, and then it was treated with alum in the same way. After permitting this fixing operation (for it may be so termed) to go on for four-and-twenty hours, the retina, in both cases, was closely observed. The result, we are told, was a clear square image, with sharply defined edges upon a beautiful rose-coloured ground. The size of the images was somewhat greater than one square millimetre, and in the first eye it was somewhat roseate in hue, and less sharply defined than in the second, which was perfectly white. That we are not romancing in all that we have said, and that our readers may not doubt the important facts which have come to us from Rome and Heidelberg, we may mention that within the last few days Mr. Arthur Gamgee, of Manchester, has repeated most of Kühne's interesting experiments, and is able to confirm them in every particular. That photo-chemical processes take place in the retina is a matter, therefore, beyond all doubt, and photographers to a man cannot but feel deeply interested in the analogy here shown to exist between the eye and the camera he uses every day.

FRENCH CORRESPONDENCE.

MÉDAILLE D'HONNEUR TO M. JANSSEN—UNFAVOURABLE REPORT ON M. SCOTELLARY'S MODE OF LIGHTING—M. LACAN'S OWN EXPERIENCES OF VIOLET LIGHT IN STUDIOS—A NEW WASHING MACHINE—BOVIN'S METHOD OF TREATING LIGHT AND DARK CARBON PRINTS.

As the medals which the French Photographic Society offered for progress during the years 1875 and 1876 have not yet been awarded, they have been transformed into a special honour medal, which was offered to M. Janssen at the last monthly meeting of the Society, held on the 2nd February. We also have to announce, with much pleasure, that among the new officers just created on the role of the Legion of Honour, the eminent astronomer also finds a place.

At the same meeting of the French Photographic

Society, the commission charged with investigating the method of lighting proposed by M. Scottelari also presented their report. The conclusions of this body are not favourable to the new system—or, at any rate, the gentlemen composing the commission have not been able to confirm the advantages attributed to the method by M. Scottelari, so far as rapidity is concerned. We do not wish to discuss the report, which, by the way, does not furnish any information of the manner in which the trials—there were three of them—were conducted; and in such matters as these the nature of the trial is necessarily of considerable importance. We are persuaded, nevertheless, that the investigation was conducted in a most conscientious spirit; but as the decision is unfavourable, we think it only right to make known what we ourselves have seen in respect to the process.

On Monday last, the 5th February, we repaired by invitation to the atelier of MM. Gillet frères, one of the studios employed for the exhibition of M. Scottelari's process. The weather, pretty fine to begin with, soon became cloudy. At a quarter past two the experiments began. The studio was divided into two parts lengthways by a violet curtain lined with blue. On the left, the window-frames, the walls, and glass were all painted violet; to the left the panes were white and transparent, and the walls painted blue. There were, therefore, two distinct galleries. The experiments began with the reproduction of a painting representing the corridor of a convent, with two nuns ascending the steps; an open window permitted the daylight to enter, and afforded a view of the country in the distance. Although the general appearance of this coloured picture was full of harmony, it offered some very vivid contrasts between the lights and shadows. M. Scottelari took a plate thirteen centimetres by eighteen centimetres, which he coated with collodion, and sensitized before us; upon one half of this plate he made the first impression in the ordinary studio, giving an exposure of two minutes; immediately afterwards, everything, apparatus, object, &c., were transported to the other side of the curtain, illuminated by violet light, and a second exposure was given upon the other half of the plate, one minute being only allowed this time. On development (the sulphate of iron solution being poured over the whole plate at one sweep), image No. 2 at once showed itself, the other coming up more tardily, and only showing in the end but faintly. The plate finished, showed on one side a very perfect and harmonious reproduction, and on the other faint details upon an absolutely transparent ground. Here, therefore, there could be no doubt of the advantage of violet illumination. Next an experiment with portraiture was made. A model was posed successively in the two studios. Thirty seconds' exposure was given, with lighting à la Rembrandt. Here, again, the result was far from doubtful. The image secured in the ordinary studio, although better brought out than in the previous experiment, showed that it suffered for want of exposure. It was hard, and almost destitute of detail. The other was harmonious, presented a delicacy of modelling which did away with the necessity of any retouching. Finally, a third trial was made. It was then twenty minutes to four, and the daylight was rapidly decreasing. The same sitter was posed again for fifteen seconds, illuminated with violet light, and then, for forty-five seconds, in the other gallery. Notwithstanding this great difference in time, however, the first of the two clichés was incontestably the better exposed of the two, more plastic, and, in a word, more successful. This is what we have ourselves witnessed, and have no hesitation in affirming; the clichés are in our own hands, and we shall be happy to show them to anybody who may desire to see them.

M. Collet (of Cherbourg) presented the Photographic Society, at its meeting of the 2nd February, with an apparatus to which he has given the name of *lanceur hydraulique*, and which is destined to fulfil in a much more prompt and

perfect manner the washing of silver prints. It consists of a little wheel with troughs carried upon a support which may be applied to all sorts of troughs in use. This wheel is put into movement by means of an india-rubber tube, which leads into the troughs water from the cistern. In this way a continuous movement is kept up in the water where the prints are washing, and the latter are consequently more satisfactorily and quickly freed from the hyposulphite than is usually the case. Many Parisian photographers have adopted the apparatus, and are doing well with it.

In a recent article in the *Moniteur de la Photographie*, my assiduous collaborateur, M. Boivin, discusses an interesting question connected with carbon printing, namely, the treatment of carbon prints that have been too much or too little exposed. When the printing has been continued too long, the image develops slowly, and remains caked, the result being too vigorous and black. To remedy matters under these circumstances, it is sufficient to drop into the development bath a few drops of a saturated and filtered solution of chloride of lime. The image gradually loses its great vigour under the action of the chloride of lime, which has the property of restoring solubility to the insolated gelatine. When the object desired has been attained, you wash with ordinary water, and then pass the print into a weak solution of hyposulphite of soda; to arrest the action of the chlorine you wash again with water, then put the print into alum and wash once more. If, on the contrary, the exposure has been too short, the image may be strengthened with the aid of the undermentioned solution, namely:

Water	100 parts
Sulphate of iron	3 "
Nitrate of iron	1 part
or a drop of nitric acid.				

After this liquid has been in contact for about a minute with the prints, the latter are washed carefully, and then treated with a very weak solution of pyrogallie or gallic acid. As soon as the requisite effect has been brought about, the prints are washed in plenty of water, and passed into the alum bath, and after a final rinse in very pure water they are allowed to dry. ERNEST LACAN.

MR. KARELINE'S WORKS, AND WHAT MAY BE GATHERED FROM THEM.

BY NORMAN MACBETH, A.R.S.A.*

No one who has witnessed the very admirable collection of photographic works lately exhibited in the Royal Academy National Gallery could have failed to notice, on entering the first room, a few very remarkable specimens of figure subjects, in direct sunlight.

When they first came under my eye, I felt that here we had a thorough mastery of light, and a kind of treatment of it which was certain to give a fresh impulse to the art, and clear away many difficulties which have seemed to be insurmountable, especially in the way of development.

Mr. Kareline (the photographer to whose works I allude) is a Russian, and I have much pleasure in taking this opportunity of congratulating him upon his success in winning the gold medal of the Edinburgh Photographic Society for the picture which, in the opinion of the judges, possessed the highest degree of merit, irrespective of size or subject.

The number of the work (according to the catalogue) which was selected was 775. It was chosen as the best embodiment of Mr. Kareline's skill and general treatment. There were other works by this gentleman which were, perhaps, finer in focus and sharper throughout; but for simplicity, good taste, fine arrangement, and breadth of effect, the work securing the first prize stands alone. Altogether, it is one of the best expositions of the

* Read before the Edinburgh Photographic Society.

general principle which seems to govern all Mr. Kareline's effects, and the chief object of this paper is to point out what appears to me to be his aim, wherein his success lies, wherein he is deficient, and the general lessons we may thus gather.

Mr. Kareline is evidently no novice in his art. His work generally manifests considerable culture, and he is apparently well acquainted with the best-acknowledged theories of composition.

The picture for which the award has been made, and to which I would now call your attention, is in size (the picture proper) 17½ by 20 inches. It is upright in form, and based upon the same composition as that to which Burnet, the engraver, calls our attention when he refers to a special picture of the Dutch school. The picture consists of a figure in light costume placed over a dark background, and another in black placed over a light one.

The subject is a domestic one, but, strictly speaking, it is portraiture treated under a familiar aspect. A husband and his wife are seated in their parlour at tea. The window of the room is visible, draped with white muslin curtains; the farthest in line of the curtain forms (vertically) almost an equal division of the picture, constituting one-half of the space in light and the other in shade. The lady is dressed in a light-coloured silk, with lace tablier over the chest and skirt of dress. She is seated and exposed to direct sunlight, over the shaded part of the background. Three-quarters of the face and body are in shadow, but under the influence of strong reflected light. The gentleman is seated close to the window, dressed in a dark grey tweed suit. His face and body are so situated in shade that they form one entire mass, and that lying over the light, composed of the window and curtains. One not acquainted with art—and especially with the expression of such strong relief as is here presented in attempting to do such a thing—might completely fail in having the composition united; but Mr. Kareline showed his skill when, by the introduction of the little table placed between the two subjects, the objects lying on it—cup, saucer, and tray cloth (being light)—join at the window on one side and on the lady's dress at the other. The objects otherwise throughout the picture, which serve to lead off the light and fill up spaces, are also skillfully arranged, and that without being too conspicuous. For instance, the great mass of shade in the back of the room is subdivided at a very fine forte point of this space by the introduction of the oil-lamp bracket and its globe. Had not that been there its want would have been felt, and the picture appear to be out of balance. Then, also, the seat of the chair behind the lady laterally distributes and carries away some of the light, which, without it, would preponderate on the lady's dress.

The treatment of lines, also, in this composition is interesting. The lady, holding an album, and the gentleman, unconsciously in the act of holding a cup (to appearance, by their unity), the lines of the arms may be said to resemble the inner lines of the capital letter M. While the main lines of the body of each resemble the outer lines of the same letter.

It is of the greatest importance that a distinct basis exist in every composition. Architects well know the value of this; the more that we can resolve upon a distinct form, by whatever way it may be suggested, the more is our design likely to be original, well connected, and varied. Mr. Kareline pays great attention to variety of forms, even in one subject. In the prize picture we have little or no repetition. The lady's head looks toward the spectator, while the head of the gentleman is in profile, and looking towards the lady. The aerial perspective of all Mr. Kareline's works is also worthy of remark. In the particular work under notice, while the extremes of light and shade are brought into juxtaposition, yet there is no violence. The lady's figure, by her light dress being placed over the shaded part of the room, becomes connected with

the background by her hair, which, being darker than the shade of the wall, appears sufficiently well made out, and, at the same time, graduated.

There are several of Mr. Kareline's works which are in better development throughout than this. Some of the shadows have not the light fully taken up in them, and there is a defective part in the wall of the background which has been restored evidently by stippling. Upon the closest inspection, this picture appears to have been printed from a negative directly taken, and not a combination. It is very little, if anything, touched-up, and never has any work been more entitled to be classed among those of which the motto holds good, "It is the highest art which conceals art." Visitors to the Exhibition (unacquainted with the art) have been greatly disappointed with this work on the first sight of it, and wondered what was to be seen in it. Painters and photographers, again, admire its simplicity of treatment, and the latter are generally puzzled as to the manner in which Mr. Kareline manages his light.

But I believe there there is no mystery in that; unquestionably, Mr. Kareline employs powerful reflectors, and at the same time has great regard to the fulfilment of natural effects. Of late, many methods of the treatment of light have been introduced, such as those styled "Rembrandt;" but the style has been too apparent, too oft repeated, and too artificial. However, it was a step in advance, and infinitely better than those effects which were the result of a glass house without any concentrated light, producing no shadows, and, consequently, no light predominating. But here—and it is one of the chief merits of Mr. Kareline's work—the main source of light is strongly marked by direct sunlight, and all the parts being in shade under the influence of treatment by reflection. The development of sunlight on the lady's face in this picture, however, has partially faded, i.e., there is not a complete realization of her complexion by reason of too dense a deposit being thrown on these parts, from which we may infer that the negative has been a little short of exposure; but in most of Mr. Kareline's work—for instance, in that of his own portrait—it is the development of the flesh tints, and the manifestation of the highest lights on fine linen, or glistening objects, such as silver or crystal, that make his works very singular. I believe the mystery of his method lies more in chemistry, and by a process of development which, if I may hazard a conjecture, it is probable, that after careful study of his arrangement, both subject of and accessories—everything prepared for action—the lens is opened and the sitters subjected to very short exposure (if not instantaneous); and by a method of development—say such as Mr. Mudd pursues in the application of plain pyro. to collodion-albumen plate—all the detail is made manifest previous to rendering by silver the respective density of parts, according to their exposure to light, or like that of Captain Abney's more recent discovery in his process of development by the application of emulsion, through which he brings out the most latent impressions of very short exposure.

(To be continued.)

LICHTDRUCK IN WATER COLOURS.

BY J. HURNIE.*

SOME six years ago I endeavoured to find an explanation for the qualities possessed by an exposed bichromated gelatine image, for the recognised theory did not appear to be satisfactory. It is usual to say that water repels the fatty pigment, and therefore in those places where the gelatine has been more or less swollen with water, less of the fatty ink attaches itself; where, however, the gelatine is not in a position to take up much water,

* Read before the Vienna Photographic Society.

there a larger quantity of the ink attaches. This answer is right enough, but it does not exhaust the question. No doubt the degree of moisture or dryness of the gelatine is the principal cause of the greater or less adherence of greasy ink, but it is not only water that repels the fatty matter, but every easily liquefied substance which possesses no stickiness. Even oil will repel a more solid and fatty substance, only it is necessary for the latter to be sticky, or in other words of a tenacious character, lengthening itself out in long threads on treatment with the roller.

In order to explain the matter more clearly, I will give a simple illustration. If we take a thick solution of gum-arabic upon the finger, and touch with this sticky substance a dry body of any kind—such, for instance, as glass or paper, or another finger for that matter—it will be found that the gummy finger will stick very close to the object it has touched. By suddenly tearing away the finger, the gummy mass is divided into two masses, of which only one half remains on the finger, while the remainder attaches to the object touched. Quite different, however, would it be if the object touched were not dry, but wet. The gummy mass no longer adheres in that case, and it may be removed again without leaving behind it a trace upon the object touched. It is necessary, indeed, to have recourse to a little friction if it is desired to rub off a little of the sticky gum upon the wet surface, so that the water mixes with the mass, and itself becomes thicker.

The same phenomenon is observed when, instead of a thick gum solution, a thick varnish or an oil colour is carried to one's finger, and the latter then first applied to a dry surface, and subsequently to one moistened with oil. In the latter case, if a thin liquid oil has been employed, there will be no adherence of the paint or varnish, as was the case with the water and gum. The finger in the last experiment is easily removed again, a small portion of the oil upon the object being carried away with the finger at the same time; so that we have direct reverse of what I previously referred to. Not only, therefore, does water repel a fatty colour, but every limpid fluid repels a thick one, even when it is a question of two bodies of the same nature, but the one of a thicker consistence than the other.

I took a very thick solution of gum-arabic, added to it glycerine and pigment, and treated therewith a Lichtdruck plate. I then found that this colouring matter attached itself in precisely the same manner as if it had been a greasy ink. The first print I secured was not a very good one, neither did I succeed with the second and the third; for it is necessary that the thickness and consistence of the ink should stand in a certain fixed relation to the dryness of the gelatine film. This relation, however, is soon brought about of itself. If the colour is too thick and the gelatine film too wet, the image takes up very little colour at all, but the colour, on the other hand, draws out some of the water from the film. In the first print, too, some of the water attaches to the paper, and the image becomes drier, so that on the second application of the colour-roller more and more ink attaches, until at last, after a little working, the Lichtdruck plate possesses just the right quantity of moisture necessary for securing good impressions. When this has been attained, the relation of dryness and moisture remains constant, and the operation continues with uniformity. The gum-colour gives at every inking as much water to the film as its condition in the different parts requires, so that by this mode of printing the manipulations of damping and sponging that have usually to be carried on fall away altogether. This method of Lichtdruck printing with water colour is, therefore, specially suited for quick-printing presses.

The gum or water colour is prepared in the following manner. Some gum-arabic is allowed to swell in water, and then as much glycerine is added as in the first place gum was employed, and the water is finally boiled quite out.

A provision of very sticky firm gum solu-

tion, which will not dry any further. To this mass any desirable quantity of colouring matter may be added. The best to use, under the circumstances, is, perhaps, ready prepared Indian ink. At the same time fine lamp-black mixed with iron-violet may be employed, water being added to the same before it is rubbed fine on a palette. When the mixture of gum and colour has been well incorporated, it is heated once more upon a copper plate to dissipate the water, and bring the compound back again once more to its former firm and solid consistence. In this condition it is that the colour is kept; on cooling it becomes yet firmer. Care must be taken in printing not to employ too much of this colour, as under these circumstances its fibrous character appears to be too short upon the roller, and the pigment fails to draw out in long threads. To employ the colour or ink, as it may be termed, it is first of all thinned down as much as desirable with glycerine—not too much, however—until it has the consistence of lithographic ink. The roller to be employed in spreading the colour must for some days previously have been saturated with glycerine, so that it will not absorb moisture from the colour itself during the operation of rolling. In printing, the same regulations are to be observed as in ordinary lithography or Lichtdruck. Too thin an ink gives flat pictures without any white lights; too thick an ink, on the contrary, yields strong shadows and white lights, and, therefore, hard pictures. The greater part of the impressions which I submit to the Society have been printed more than six years, and still remain unchanged.

The pictures, if properly printed, are dry as soon as they are produced; the colouring matter is already very dry when applied, so as to be incapable of being smeared, and any superfluous moisture is absorbed by the paper bearing the impression. The paper must be moistened to a certain degree when put into the press, as otherwise it would absorb moisture too greedily from the gelatine printing block, and it would then be necessary to pass and repass the roller many times to re-establish the proper balance of moisture and dryness. If a gelatine block becomes robbed of its moisture altogether, it will begin to take up colour all over its surface, and then the image will appear quite black. It is necessary, as I have already said, to roll the plate for a long time until the gelatine has again absorbed sufficient moisture from the ink itself. If properly manipulated, this constant relation between ink and plate may be maintained without difficulty, and the printing then goes on with considerable rapidity.

The prints produced in this manner will bear treatment with water, gelatine, or varnish, so that any medium almost may be made use of to secure a high polish if it is desired. Only it must be borne in mind that the pictures must not be rubbed in a moist condition, as they are easily smudged. This disposition of the picture to become injured by rubbing when in a moist condition is, in fact, the only way to tell of the presence of water-colour, and the only defect as compared to prints in lithographic ink. If none of these pictures are ever permitted to come into contact with wet objects, the practice of water-colour printing in this manner is without a defect; while by following the method I have pointed out, many great advantages are secured by working in the manner indicated. The colours or inks employed are cheaper, and, at the same time, do not possess the inconvenience of drying in their tubes or boxes, and, for this reason, no loss need be apprehended by keeping them. The rollers retain their elasticity for a much longer period, and no hard crusts form upon the surface which have to be continually scraped off with a spatula, as in the case of lithographic work. Again, the hands are much more easily washed and freed from dirt, as, indeed, is the case with the blocks and rollers, &c. Finally, the air is not full of unpleasant odours of turpentine, and the work may be carried on, therefore, far more pleasantly.

ON SENSITIZING THE COLLODION FILM.

BY J. KAY.

AFTER the plate is collodionised, it is sensitized by immersion in the silver bath. And how long ought the plate to remain in the silver solution? This is a question of importance. I scarcely know of another so important. Unfortunately, it is one that cannot be answered in a short sentence. When I look through many of the negatives that are produced in some establishments, I find that the principle involved in this question is not understood there. Some teachers have said that when the plate is first put into the bath, it must be kept in continual motion until all traces of "greasiness" have disappeared; it is then time to withdraw it. That may be quite true under many conditions, but the teaching itself is defective. It leads one to suppose that the absence of "greasiness" is the all-important determining point. When we come to inquire into the facts of the case, we very soon see that the thing to be obtained by the immersion of the plate in the silver solution is the sensitiveness of the collodion film. And, in answering the question with which I started, we must know what the exact character of the sensitizing solution is.

An error prevails among many photographers when they suppose that with a new bath the plate requires rapid immersion. Rapid immersion may be necessary with a new bath under certain circumstances, but I maintain that the point to be determined is not the age of the bath, but its condition. Here is a new bath of 90 ounces, strength 40 grains, slightly acidified, and saturated with iodide. Let us try a plate on the theory of "movement until all traces of 'greasiness' have disappeared." The time required for the working of this theory is very short—just about a minute. Exposed, developed, and fixed, we have a negative which has all the elements of an imperfectly sensitized film. I have seen hundreds of such negatives, nothing in them, no quality; they appear to be under-exposed; and yet, when put against the coat sleeve, one can see that they are well exposed. The printer dreads the sight of such negatives—they are exceedingly difficult to print, and the prints even more difficult to tone. With such negatives I have known operators condemn, in unmeasured terms, collodion, bath, developer, glass house, light, and, in short, every thing but the right thing. We will try another plate in the same bath, recollecting, however, the most important thing of all—namely, its condition—highly iodized. We need not, therefore, be afraid of the plate remaining in the bath after "all traces of 'greasiness' have disappeared." We will let it remain in the bath, say, for five or six minutes. Exposed, developed, and fixed, we have before us a negative as much like the other as "chalk is like cheese." The plate fully sensitized, the negative is in every respect satisfactory.

Here is another new bath containing the same quantity as the last, and of the same strength, but *not* iodized. In this case, we will follow the plan of many excellent operators who iodize by immersing a collodionised plate, 8½ by 6½, in the bath, and leaving it there all night. The bath now is—well, I won't say only partially iodized, it is not saturated with iodide. We shall have proof of that presently. Now, in this case, and under these conditions, the thing required in sensitizing is rapid immersion. Should the plate be left in the bath many minutes, the collodion will lose its sensitive properties, commencing from that part of the plate where the deposit is the thinnest; and this is the proof that we have that the bath is not saturated with iodide.

Let operators—especially those of scanty experience—use largely and unparaphrasingly of that all-important ingredient of all photographic formulae, brains, and observe the conditions and circumstances under which good and bad negatives are obtained, and they will rarely, if ever, be bothered and perplexed, as many are, by a remarkably good negative

this time, and a remarkably indifferent one the next. I would recommend baths saturated with iodide. For my own part, I do not think that you can over-iodize. At any rate, I find it to be safer to work with highly iodized baths than otherwise.

Just one thing in conclusion. I ought to say that the effects which I have indicated as arising from a rapid immersion of the plate in a bath highly iodized may, to some slight extent, be obviated by keeping the plate out of the bath for a considerable time before developing. This, indeed, is done in many establishments when several positions are taken on one plate.

I enclose one or two prints from negatives sensitized in a highly iodized bath.

[The prints enclosed are very fine indeed.—Ed.]

M. BOIVIN'S METHOD OF TREATING THE SILVER BATH.*

Of all the methods described for ascertaining the strength of one's silver bath, there is none I have found more convenient to use, and more economical, than that herein referred to. The apparatus required is of the simplest description. I take a graduated burette marked off into cubic centimetres, which may be purchased of any purveyor of scientific apparatus. Into this apparatus I pour some of the undermentioned liquid as far as the mark 0; namely,—

Distilled water	...	1000 cub. cent.
Dry chloride of sodium	...	6.9 grammes
Bichromate of potash	...	1 gramme

I next take a test-tube, and introduce into it precisely two cubic centimetres of the silver solution, the strength of which I want to discover. I hold this test-tube under my burette, and from the latter permit the liquid to fall drop by drop.

The burette being provided by a means whereby the solution of salt it contains may be allowed to escape drop by drop, it is an easy manner to regulate the amount of liquid that falls into the test-tube.

The purple precipitate at first formed by the falling of the liquid into the test-tube soon passes to white, and the moment this happens the operator looks at his burette to see how much liquid has escaped to bring about this result. The figure or degree marked upon the glass denotes the weight of nitrate of silver contained in every hundred cubic centimetres of the liquid under examination.

It is very preferable to employ this means of estimating the silver contained in a solution rather than the argentometers and other apparatus in general use with photographers, as these are often affected by salts contained in the solution other than those of silver. In the method above described, on the other hand, it is only silver salts that influence the test.

ALBUMEN SUBSTRATUM.—A correspondent says:—"I notice the remarks in your journal as to the use of an albumen substratum to collodion films, and can bear my testimony to the immense amount of ill-usage which a film with albumen substratum will bear without injury. In a first attempt (encouraging, but not quite successful) which I made yesterday to produce a transparency with nitric acid, &c., as detailed in your YEAR-BOOK, I used one of Ohambers' uranium dry plates developed with alkaline pyro, then flooded with strong nitric acid; then redeveloped and fixed; then twice flooded with chloride of gold solution, and twice again with alkaline developer. The plate, which has an albumen substratum, actually bore all this ill-usage without the film giving way."

* *Monsieur de la Photographie.*

there a larger quantity of the ink attaches. This answer is right enough, but it does not exhaust the question. No doubt the degree of moisture or dryness of the gelatine is the principal cause of the greater or less adherence of greasy ink, but it is not only water that repels the fatty matter, but every easily liquefied substance which possesses no stickiness. Even oil will repel a more solid and fatty substance, only it is necessary for the latter to be sticky, or in other words of a tenacious character, lengthening itself out in long threads on treatment with the roller.

In order to explain the matter more clearly, I will give a simple illustration. If we take a thick solution of gum-arabic upon the finger, and touch with this sticky substance a dry body of any kind—such, for instance, as glass or paper, or another finger for that matter—it will be found that the gummy finger will stick very close to the object it has touched. By suddenly tearing away the finger, the gummy mass is divided into two masses, of which only one half remains on the finger, while the remainder attaches to the object touched. Quite different, however, would it be if the object touched were not dry, but wet. The gummy mass no longer adheres in that case, and it may be removed again without leaving behind it a trace upon the object touched. It is necessary, indeed, to have recourse to a little friction if it is desired to rub off a little of the sticky gum upon the wet surface, so that the water mixes with the mass, and itself becomes thicker.

The same phenomenon is observed when, instead of a thick gum solution, a thick varnish or an oil colour is carried to one's finger, and the latter then first applied to a dry surface, and subsequently to one moistened with oil. In the latter case, if a thin liquid oil has been employed, there will be no adherence of the paint or varnish, as was the case with the water and gum. The finger in the last experiment is easily removed again, a small portion of the oil upon the object being carried away with the finger at the same time; so that we have direct reverse of what I previously referred to. Not only, therefore, does water repel a fatty colour, but every limpid fluid repels a thick one, even when it is a question of two bodies of the same nature, but the one of a thicker consistence than the other.

I took a very thick solution of gum-arabic, added to it glycerine and pigment, and treated therewith a Lichtdruck plate. I then found that this colouring matter attached itself in precisely the same manner as if it had been a greasy ink. The first print I secured was not a very good one, neither did I succeed with the second and the third; for it is necessary that the thickness and consistence of the ink should stand in a certain fixed relation to the dryness of the gelatine film. This relation, however, is soon brought about of itself. If the colour is too thick and the gelatine film too wet, the image takes up very little colour at all, but the colour, on the other hand, draws out some of the water from the film. In the first print, too, some of the water attaches to the paper, and the image becomes drier, so that on the second application of the colour-roller more and more ink attaches, until at last, after a little working, the Lichtdruck plate possesses just the right quantity of moisture necessary for securing good impressions. When this has been attained, the relation of dryness and moisture remains constant, and the operation continues with uniformity. The gum-colour gives at every inking as much water to the film as its condition in the different parts requires, so that by this mode of printing the manipulations of damping and sponging that have usually to be carried on fall away altogether. This method of Lichtdruck printing with water colour is, therefore, specially suited for quick-printing presses.

The gum or water colour is prepared in the following manner. Some gum-arabic is allowed to swell in water, and then as much glycerine is added as in the first place gum was employed, and the water is finally boiled quite out. You now have a provision of very sticky firm gum solu-

tion, which will not dry any farther. To this mass any desirable quantity of colouring matter may be added. The best to use, under the circumstances, is, perhaps, ready prepared Indian ink. At the same time fine lamp-black mixed with iron-violet may be employed, water being added to the same before it is rubbed fine on a palette. When the mixture of gum and colour has been well incorporated, it is heated once more upon a copper plate to dissipate the water, and bring the compound back again once more to its former firm and solid consistence. In this condition it is that the colour is kept; on cooling it becomes yet firmer. Care must be taken in printing not to employ too much of this colour, as under these circumstances its fibrous character appears to be too short upon the roller, and the pigment fails to draw out in long threads. To employ the colour or ink, as it may be termed, it is first of all thinned down as much as desirable with glycerine—not too much, however—until it has the consistence of lithographic ink. The roller to be employed in spreading the colour must for some days previously have been saturated with glycerine, so that it will not absorb moisture from the colour itself during the operation of rolling. In printing, the same regulations are to be observed as in ordinary lithography or Lichtdruck. Too thin an ink gives flat pictures without any white lights; too thick an ink, on the contrary, yields strong shadows and white lights, and, therefore, hard pictures. The greater part of the impressions which I submit to the Society have been printed more than six years, and still remain unchanged.

The pictures, if properly printed, are dry as soon as they are produced; the colouring matter is already very dry when applied, so as to be incapable of being smeared, and any superfluous moisture is absorbed by the paper bearing the impression. The paper must be moistened to a certain degree when put into the press, as otherwise it would absorb moisture too greedily from the gelatine printing block, and it would then be necessary to pass and repeat the roller many times to re-establish the proper balance of moisture and dryness. If a gelatine block becomes robbed of its moisture altogether, it will begin to take up colour all over its surface, and then the image will appear quite black. It is necessary, as I have already said, to roll the plate for a long time until the gelatine has again absorbed sufficient moisture from the ink itself. If properly manipulated, this constant relation between ink and plate may be maintained without difficulty, and the printing then goes on with considerable rapidity.

The prints produced in this manner will bear treatment with water, gelatine, or varnish, so that any medium almost may be made use of to secure a high polish if it is desired. Only it must be borne in mind that the pictures must not be rubbed in a moist condition, as they are easily smudged. This disposition of the picture to become injured by rubbing when in a moist condition is, in fact, the only way to tell of the presence of water-colour, and the only defect as compared to prints in lithographic ink. If none of these pictures are ever permitted to come into contact with wet objects, the practice of water-colour printing in this manner is without a defect; while by following the method I have pointed out, many great advantages are secured by working in the manner indicated. The colours or inks employed are cheaper, and, at the same time, do not possess the inconvenience of drying in their tubes or boxes, and, for this reason, no loss need be apprehended by keeping them. The rollers retain their elasticity for a much longer period, and no hard crusts form upon the surface which have to be continually scraped off with a spatula, as in the case of lithographic work. Again, the hands are much more easily washed and freed from dirt, as, indeed, is the case with the blocks and rollers, &c. Finally, the air is not full of unpleasant odours of turpentine, and the work may be carried on, therefore, far more pleasantly.

ON SENSITIZING THE COLLODION FILM.

BY J. KAY.

After the plate is collodionized, it is sensitized by immersion in the silver bath. And how long ought the plate to remain in the silver solution? This is a question of importance. I scarcely know of another so important. Unfortunately, it is one that cannot be answered in a short sentence. When I look through many of the negatives that are produced in some establishments, I find that the principle involved in this question is not understood there. Some teachers have said that when the plate is first put into the bath, it must be kept in continual motion until all traces of "greasiness" have disappeared; it is then time to withdraw it. That may be quite true under many conditions, but the teaching itself is defective. It leads one to suppose that the absence of "greasiness" is the all-important determining point. When we come to inquire into the facts of the case, we very soon see that the thing to be obtained by the immersion of the plate in the silver solution is the sensitiveness of the collodion film. And, in answering the question with which I started, we must know what the exact character of the sensitizing solution is.

An error prevails among many photographers when they suppose that with a new bath the plate requires rapid immersion. Rapid immersion may be necessary with a new bath under certain circumstances, but I maintain that the point to be determined is not the age of the bath, but its condition. Here is a new bath of 90 ounces, strength 40 grains, slightly acidified, and saturated with iodide. Let us try a plate on the theory of "movement until all traces of 'greasiness' have disappeared." The time required for the working of this theory is very short—just about a minute. Exposed, developed, and fixed, we have a negative which has all the elements of an imperfectly sensitized film. I have seen hundreds of such negatives, nothing in them, no quality; they appear to be under-exposed; and yet, when put against the coat sleeve, one can see that they are well exposed. The printer dreads the sight of such negatives—they are exceedingly difficult to print, and the prints even more difficult to tone. With such negatives I have known operators condemn, in unmeasured terms, collodion, bath, developer, glass house, light, and, in short, every thing but the right thing. We will try another plate in the same bath, recollecting, however, the most important thing of all—namely, its condition—highly iodized. We need not, therefore, be afraid of the plate remaining in the bath after "all traces of 'greasiness' have disappeared." We will let it remain in the bath, say, for five or six minutes. Exposed, developed, and fixed, we have before us a negative as much like the other as "chalk is like cheese." The plate fully sensitized, the negative is in every respect satisfactory.

Here is another new bath containing the same quantity as the last, and of the same strength, but not iodized. In this case, we will follow the plan of many excellent operators who iodize by immersing a collodionized plate, 8½ by 6½, in the bath, and leaving it there all night. The bath now is—well, I won't say only partially iodized, it is not saturated with iodide. We shall have proof of that presently. Now, in this case, and under these conditions, the thing required in sensitizing is rapid immersion. Should the plate be left in the bath many minutes, the collodion will lose its sensitive properties, commencing from that part of the plate where the deposit is the thinnest; and this is the proof that we have that the bath is not saturated with iodide.

Let operators—especially those of scanty experience—use largely and unsparringly of that all-important ingredient of all photographic formulae, brains, and observe the conditions and circumstances under which good and bad negatives are obtained, and they will rarely, if ever, be bothered and perplexed, as many are, by a remarkably good negative

this time, and a remarkably indifferent one the next. I would recommend baths saturated with iodide. For my own part, I do not think that you can over-iodize. At any rate, I find it to be safer to work with highly iodized baths than otherwise.

Just one thing in conclusion. I ought to say that the effects which I have indicated as arising from a rapid immersion of the plate in a bath highly iodized may, to some slight extent, be obviated by keeping the plate out of the bath for a considerable time before developing. This, indeed, is done in many establishments when several positions are taken on one plate.

I enclose one or two prints from negatives sensitized in a highly iodized bath.

[The prints enclosed are very fine indeed.—Ed.]

M. BOIVIN'S METHOD OF TREATING THE SILVER BATH.*

Of all the methods described for ascertaining the strength of one's silver bath, there is none I have found more convenient to use, and more economical, than that herein referred to. The apparatus required is of the simplest description. I take a graduated burette marked off into cubic centimetres, which may be purchased of any purveyor of scientific apparatus. Into this apparatus I pour some of the undermentioned liquid as far as the mark 0; namely,—

Distilled water	...	1000 cub. cent.
Dry chloride of sodium	...	6.9 grammes
Bichromate of potash	...	1 gramme

I next take a test-tube, and introduce into it precisely two cubic centimetres of the silver solution, the strength of which I want to discover. I hold this test-tube under my burette, and from the latter permit the liquid to fall drop by drop.

The burette being provided by a means whereby the solution of salt it contains may be allowed to escape drop by drop, it is an easy manner to regulate the amount of liquid that falls into the test-tube.

The purple precipitate at first formed by the falling of the liquid into the test-tube soon passes to white, and the moment this happens the operator looks at his burette to see how much liquid has escaped to bring about this result. The figure or degree marked upon the glass denotes the weight of nitrate of silver contained in every hundred cubic centimetres of the liquid under examination.

It is very preferable to employ this means of estimating the silver contained in a solution rather than the argentometers and other apparatus in general use with photographers, as these are often affected by salts contained in the solution other than those of silver. In the method above described, on the other hand, it is only silver salts that influence the test.

ALBUMEN SUBSTRATUM.—A correspondent says:—"I notice the remarks in your journal as to the use of an albumen substratum to collodion films, and can bear my testimony to the immense amount of ill-usage which a film with albumen substratum will bear without injury. In a first attempt (encouraging, but not quite successful) which I made yesterday to produce a transparency with nitric acid, &c., as detailed in your YEAR-BOOK, I used one of Chambers' uranium dry plates developed with alkaline pyro, then flooded with strong nitric acid; then redeveloped and fixed; then twice flooded with chloride of gold solution, and twice again with alkaline developer. The plate, which has an albumen substratum, actually bore all this ill-usage without the film giving way."

M. KARY'S SYSTEM OF LIGHTING.

ABOUT twelve months ago we called the attention of our readers to the announcement of a new system of lighting claimed by M. Kary, a photographer in Algiers. M. Kary's system was described in a pamphlet issued to subscribers at the rate of one hundred francs (£4) for each copy. Our editorial correspondent, Mr. Charles Waldack, informed us at the time that the system was based on the use of screens both for increasing light by reflection, and softening it by shutting the model; and that a similar system had been described in our columns as the practice of Mr. Myers, an American photographer. From another source we learnt that M. Kary used hand-screens covered with white, blue, pale tints of red and orange, and other colours according to the result required.

We have recently received from M. Kary a somewhat extensive circular calling attention to his pamphlet, and to the notices from many authorities of his system and its results, including the names of many distinguished practical photographers and scientific men in France. One of our correspondents, Mr. F. Row, of Braintree, has recently favoured us with a sight of some of M. Kary's specimens, which are certainly very fine, and manifestly the work of a man of thoroughly artistic feeling; the lighting and treatment generally are decidedly good. As we have repeatedly before said, we believe that the use of portable screens and reflectors as adjuncts in securing effective and harmonious lighting of the model has not received half the attention of which it is worthy; and we hope that M. Kary's work will be extensively read, as, judging from the opinions of practical men like Fritz Luckhardt, of Vienna, and others, the principles of lighting photography are ably treated. As we are writing for the information of our readers, rather than to advertise M. Kary's pamphlet, it is sufficient to add here, that M. Kary sends out his little work in English translation, and his address is Gallery Malakoff, Algiers. Those interested in the description of Mr. Myers, to which we have referred, will find full details in our eighteenth volume, and also the *Photographic News* of last March 17th, p. 127.

A point to which Mr. Kary calls especial attention is the relation in time of exposure which his system of using screens permits. This may readily be understood. An old and excellent rule in relation to exposure is, "Expose for the shadows, the light will then take care of themselves;" and the long exposure at times required in portraiture is rarely required for the same or much as for

some deep shadow in drapery, or for the hair. By the use of portable reflectors these obscurely-lighted portions can be made to receive a greater amount of light, rather than a longer period of the ordinary lighting. This would manifestly confer an advantage, as the prolonged exposure required by the dark portions of the model often burns out the detail from lighter portions. In like manner, extremely light portions of drapery, which really require a shorter exposure than the sitters, and drapery generally, may have the light carefully screened off during the whole or a part of the exposure. The advantages of a merely technical kind gained by the use of portable screens are very valuable; but they are comparatively trifling and subsidiary to the aid they afford the artist in producing pictorial effect, of which the introduction and uniting of shadows is such an important part. A photographer should always remember that the mere representation of an object is not a picture, unless by the management of light and shadow it presents what is recognized as pictorial effect. And there is no aid to the introduction and control of light and shadow like the portable screen, which, in the hands of an artist, would produce in every portrait a picture. Let the young portraitist try this, practicing awhile first with plaster models, placing them in full light, and then try what variety of effect of light and shade may be produced by the use of screens alone during exposure. The lessons gained in such practice will be most valuable. Some idea of the use of such screens having been gained, then try to produce specific effects of lighting, such as may be seen in the works of the great portraitists. We are not here recommending imitation to portraitists, although we do not say that photographers might not often, if they can, imitate the work of great painters with advantage. But we have been in these remarks merely recommending a certain course for educational practice. Until the portraitist has mastered the use and management of screens, we should not recommend him to introduce them into his daily practice, as he may easily miss the result at which he aims, and startle his sitters. Skill and judgment should, of course, govern the use of the screen in actual practice.

A PAINTER ON THE EDINBURGH EXHIBITION.

THE days when hot discussions were maintained as to the art claims of photography are happily over. We may happily, because no amount of discussion affected the fact, nor seriously affected the recognition or denial of the art claims made of our art science. Whatever the art claims of photography may be, it has always been affiliated to art. Daguerre was an artist, and the earliest and ablest of photographers have generally had artistic training. The first president of the Photographic Society was also the president of the Royal Academy, Sir Charles Eastlake, one of its vice-presidents being another artist, Sir Wm. Newton. The president of the Royal Scottish Academy, and an Associate of the same Academy, were members of the recent jury of award at Edinburgh; and now we find the same Associate of the Royal Scottish Academy, a painter of great ability, delivering a lecture full of interest and instruction on the contributions of the first prize man at the Exhibition. More than once, incidentally, the speaker repudiated the idea of art claims for photography. But photographers may find consolation in the fact that he criticized the prize picture of M. Karelina as a work of art, and pointed out how the art qualities were secured by decidedly formative process: breadth, as he showed, being obtained by uniting the masses of light and shadow by the accessories on the table. Our object, here, is not to revive the discussion, or insist on art qualities in photography; but to commend a careful study of the criticism to portraitists, who may, without seeing the picture, realize the composition and the management of its art qualities from the remarks of Mr. Macbeth.

MESSRS. BURROWS AND COLTON'S RETOUCHING DESK.

THE legitimacy of retouching as a desirable aid to excellence of result, having, we think, been satisfactorily demonstrated in these pages, every aid and appliance which can facilitate such work, or facilitate excellence in executing it, becomes of vital importance. The retouching desk devised by Messrs. Burrows and Colton comes pre-eminently within the category of such aids. A desk which enables the retoucher to see perfectly his work, get at it with ease and facility, and continue working with precision and comfort, must materially tend to excellence in result.

This desk is manifestly the outcome of experience, the invention of one who has felt what was wanted. The diagram will give an idea of the general arrangement of

the frame, which is good, but not essentially novel; it is in the special appliances that unusual advantages will be found. In the first place, it is full of convenient adjustments to any position or mode of working. The retoucher may as easily sit upright to the work, as in a leaning round-shoulder-inducing position. Of the base we need not say more than that it contains a drawer for holding loose portions of the desk, pencils, &c., and is provided with a pencil sharpener in a handy position. Attached to the base is the desk proper, which can be placed at any suitable angle. It is provided with a circular revolving inner frame, with clamping screws, sliding in a groove to permit them to hold firmly negatives of various sizes. Behind a central aperture in this revolving table or stage is an attachment on the principle of a series of revolving diaphragms, containing three apertures, any one of which can, on revolving the disc in which they are contained, be brought immediately behind the aperture in the desk, over which the negative rests during retouching. This arrangement affords a most ingenious facility for modifying the lighting through the negative. Every one who has attempted retouching negatives is familiar with the fact that much of the comfort of working, and much of the character of the finished work, depends upon the lighting of the negative during the operation. In this revolving disc, in each of the three apertures is a different kind of glass; one plain clear glass, one fine ground glass, and one opal glass. This arrangement enables the manipulator to judge with accuracy as to the effect of his work on the negative, and guides him in modifying the amount or style of the work he is applying. Placed underneath the desk in a proper position on the base is a concave silvered reflector, for throwing up a satisfactory light on the negative, which is of great value, either for daylight or artificial light. As the circular table or stage in the desk readily revolves, the artist is enabled to bring

the negative in a moment into a satisfactory position for working on.

By no means the least important adjunct to this desk is the magnifying-glass, attached to a steady, movable arm of brass, with adjustment to place it in any position and at any focus to suit the artist. The importance of steadiness in the position of the magnifier cannot be overestimated in saving the eyes of the workman.

The desk, when closed, packs up into a convenient flat space.

We find that after a verbal enumeration and description of the varied convenient appliances which appertain to this desk, but a meagre idea is given of its actual completeness and efficiency. But we have no hesitation in giving it our heartiest commendation, and remarking that as Messrs. Burrows and Colton have produced the best book on retouching which has been issued, they have also produced beyond all comparison the best desk for aiding in producing good work and securing the convenience and comfort of the retoucher.

TINTING AND GLAZING PICTURES.

IN a recent number of the *Archiv* there appears a note by M. Stuting, recommending the employment of aniline-violet to improve the tone of gelatinized prints. This gentleman states that albumenized prints which receive a coating of gelatine to increase their brilliancy not unfrequently appear more yellow in the whites than was previously the case, and this defect, he states, may be avoided by the application of a small quantity of aniline-violet.

The glazing of the picture is undertaken in the ordinary way, but previously to the prints being laid down upon the gelatine or collodionized glass they are first of all put into a weak solution of aniline violet. This solution must be quite free from dust, and the pictures must be dipped into it face downwards; any particle of dust causes minute spots of deep colour, which are not to be removed subsequently. The tinting of the photograph in this manner annuls the yellow tone of the whites, which is often exaggerated when by the gelatine coating. The pictures should be vigorously printed, and toned of a brownish colour, so that they may not appear weak when glazed. This tinting with aniline-violet may be recommended also for large portraits, to which it imparts a beautiful and luscious tone.

M. Stuting is quite right in attempting to counteract the yellowness which some gelatinized prints undoubtedly possess, but the use of aniline colours, as a rule, is scarcely to be recommended, from the circumstance that they are so liable to fade. However, if it is desired to employ such pigments upon photographs, without giving them that high brilliancy which gelatine and collodion spread upon glass always imparts, they may with facility be dissolved in normal collodion, and this poured over the mounted or unmounted picture in the same way as if one were coating a plate.

THE AUBELDRUCK PROCESS.

A good deal of speculation is rife in regard to this mechanical printing process, which has attracted a good deal of attention in Germany. It is the invention of M. Aubel, of Cologne, and its results (though far from perfect at present) show considerable vigour and depth, which Lichtdruck prints not unfrequently lack. The Aubeldruck printing blocks are of metal, and may be worked in the printing press, so that for this reason alone the process has much to recommend it.

The manner in which M. Aubel converts a negative into a printing block is still maintained a close secret; but a German journal, the *Arbeitsgeber*, professes to have found out the secret. A negative of any design, sketch, or writing is

black and white, is secured; and the silver deposited upon the glass plate to form the image is then strengthened by further deposition of silver by means of the electrolyte process. A couple of hours suffices to make the deposit of metal thick enough, and then the image upon the glass is submitted to the action of hydro-fluoric acid vapour. This vapour attacks the glass in all parts where it is not covered with silver, and in a little while there is produced upon the glass the image in relief.

We suppose that from this a galvano-plastic image is taken, which constitutes the block for printing purposes, for it would never do, of course, to use plate-glass in a printing press; and for this reason, probably, a positive, and not a negative, would be required in the first instance. This, however, is a mere matter of detail, and does not, in any way, touch the principle of the process.

In another German journal—the *Archiv*—appears a letter, also touching upon the Aubel process, in which it is stated that according to some experiments undertaken by the author, M. E. Selinger, he is of opinion that it is not a silver image that is employed to cover the glass, and thus prevent the action of the hydrofluoric acid fumes, but lead, with which the original negative is intensified. There is every probability, we think, of such being the case. In the first place, it is very difficult to deposit silver equally upon a negative film by the aid of a galvanic battery, as in the electrolyte process, while, on the other hand, the process of intensifying by the aid of nitrate of lead, as recently pointed out by those thorough experimentalists MM. Eder and Toth, is a very facile one to carry out. Moreover, nitrate of lead, applied in this manner to a photographic film, has the effect of depositing a very dense film of that metal upon the glass plate, and lead, as chemists know, is not attacked by hydrofluoric acid fumes. We cannot, therefore, but doubt that the plan suggested by M. Selinger is the one adopted by M. Aubel in the production of his plates, as affording the most simple and certain method of proceeding.

Anent the use of lead as an intensifier, we may here record an interesting experiment. We have for some months past been witness to the employment of the nitrate of lead intensifier of MM. Eder and Toth. If only care is employed in using distilled water in the washing, there is no chance whatever of staining, and the most perfect photo-lithographic negatives, with the blackest of grounds, may be secured with it. The other day, however, our attention was called to a glass plate upon which a drawing had been photographed and intensified with lead. For some reason or other the picture was a failure, and the film consequently washed off, and the plate put by for further use. On a close examination of it, subsequently, there was found etched upon its surface, in dull lines, the photographic image. Every line was sharp and clear, and could only be removed by considerable friction. Here is a hint that should be useful both to glass etchers and to the producers of spirit photographs.

Correspondence.

NORTHERN NOTES.

SIR,—We are not nearly tired of the Edinburgh Photographic Exhibition. The photographers there are greatly exercised by some of Karelino's pictures. It is said that the medal has been given more in consideration of inexplicable lighting than from any great merit they possess. Now, this must be the invention of a disappointed exhibitor, although I must acknowledge that I could look at them without going into fits; and having seen them, I must say that there is nothing mysterious about them. The medal group is taken at a single exposure, in a room or studio; through a window streams of sunlight fall upon two figures. The shadow side may be softened by a reflector or distant window. To say that the picture is taken in Russia is half the mystery solved; for every picture I have seen from that

region gives evidence of a clear transparency in the atmosphere which we once or twice in a life-time experience.

The Glasgow Photographic Association advertises lately "that a number of the Edinburgh Exhibition prize photographs" would be on view at the Gallery of the Society. It is further intended to sit on the prize picture at an early meeting of the Association. I wonder if the Glasgow men will be pleased with the "Portrait of a Gentleman," by James Howie. Surely they will, for though "this work does not contain much treatment," yet it is a "specimen of very true rendering without the aid of modelling the negative." Now, we Glasgow photographers hate modelling. They told Mr. Henderson, of Perth, a week or two ago, that they hated it. And so they may, for almost every one of them are slaves to retouching, or what is termed by a South of England photographer as "the Florentine system," which renders all freckles and imperfection in the skin imperceptible.

What became of our Lambertype, chromotype, and contotype friends? From the number of licensees in Scotland I expected to see any number of Lambertype enlargements by men who had seen the skilful M. Lambert touch up a negative; but I was disappointed. From this week's News I find that they do these things better in America. I was greatly surprised to see so long a letter in the *British Journal* by Mr. A. L. Henderson. It was not the bit about the hot weather of America I liked the best, nor the bit on carbon, but Jules Verne's "Round the world in eighty days," condensed by Mr. Henderson, is worthy of this special notice.

The enlargements exhibited by some of the Northerners had a tendency to flatness; the backgrounds too much the colour of slate. The artists in black and white over-do the thing. Like touching on the negative, this black-and-white fashion is being carried to an alarming extent. What will the Autotype Company say to this? Scotland is now in possession of two firms who do enlarging for the trade—G. W. Wilson and Co., of Aberdeen, and Annan and Skelton, of Glasgow. Both of these firms have on their staff men who were at Ealing De:n, certainly the best school. It was once supposed necessary to make arrangements with the Autotype Company for special licenses to do carbon work for the trade; but I suppose any one can enlarge for the trade now with impunity. One of your correspondents says openly that he is practising permanent printing, and that it is free. Surely I remember of the Company giving notice that they only supplied tissue to licensees. Am I right? These carbon patents were very loose from the first; and would it not be hard if the licensees were to find that they could not be protected? Chromotype is without doubt the process of the future; but there are many men thinking that if they could only get the tissue independent of the Autotype Company, permanent printing would have their immediate attention. Some pretty successful experiments at tissue-making have been tried about Glasgow. Messrs Sawyer and Bird will, no doubt, keep a sharp eye on Glasgow. I was surprised to see Mr. Ferranti speaking for the photographers of Edinburgh, or rather for Mr. Ayton. If they do not learn the chromotype process, and that very soon, where will they be? Let them answer for themselves.—Yours truly, Jo. VESTRIS.

ORIGIN OF PROTONITRATE DEVELOPMENT.

DEAR SIR,—I take the PHOTOGRAPHIC NEWS for the sake of *auld lang syne*; but I did not chance to see the numbers in June and July last until weeks after publication, and I was not a little surprised to find my name cropping up again in matters photographic. I am sure neither Mr. Spiller nor myself would wish to rob the introducer of the protonitrate developer of an atom of the merit. I must say, however, that Dr. Diamond seems (in his letter of June 30th, and again in his paper in the Year-Book) to be hitting rather hard at Mr. Spiller and myself, and in a way which I do not think we deserve

Mr. Spiller and I were dissatisfied (as most of those who tried it were—vide "Notes and Queries" 1853) with the unstable protonitrate made with baryta; and we tried to remedy that defect by other formulæ. I certainly did not know that all available nitrates had been tried. As no one else had published our methods, and as the solutions made by us would keep a considerable time, I maintain, in contradiction to Dr. Diamond, that we had reason for publishing (as improvements) the use of nitrates of lead and potash. Dr. Diamond's reasoning would bar all other experiments when he, "after innumerable experiments, has discovered the marvellously fine effects" of any chemical. As to the undoubted beauty resting with the baryta salt, I join issue with Dr. Diamond, and for the purpose of comparison will willingly forward you some positives, taken twenty-four years ago. I need not say that I should pay the carriage to you and back.

Before I possessed a camera, I had tried all the processes I could which I found in Mr. Hunt's book, and had read there something about protonitrate as a developer before I ever saw "Notes and Queries." My edition is the first preface, dated July 1851. Dr. Diamond's name does not occur in that edition, but in the same paragraph in which Mr. Hunt speaks of showing at York, in 1844, a series of photographs developed with protosulphate of iron, which salt he says "was most effective in developing any photographic images on whatever argentiferous preparation they may have been received." He goes on: "Mr. Robert Ellis has recommended the use of protonitrate of iron as a developing agent."

We were much indebted to Dr. Diamond for the trouble he took in rendering photography popular; but I do not think it is quite fair that he should come down so heavily on Mr. Spiller and myself because we had the misfortune to suggest the lead and potash formulæ. I can quite understand how Dr. Diamond's name was mentioned in the third edition. Mr. Home told Mr. Hunt that he understood protonitrate of iron answered equally well as the pyrogallie acid; and, probably, Dr. Diamond or Mr. Archer had told Mr. Home this (see page 146).

I ask you in fairness to insert this letter in your next number.—I am, dear sir, yours truly, J. LAWSON SISON.

Edingthorpe Rectory, North Walsham, Norwich.

[We have always pleasure in hearing from our old correspondent, the Rev. J. Lawson Sison; but we regret that it should be in connection with anything in which he should think he has received scant courtesy or justice. That no slight was intended by Dr. Diamond we could have declared unhesitatingly, and we are, indeed, authorized to assure Mr. Sison of that fact. Regarding the origin of the protonitrate developer, we accept Mr. Hunt's book as, probably, the best historic authority, and beg to refer our correspondent to page 264 of the third edition to which he refers, where he will find Mr. Hunt, after describing the beautiful results of the protonitrate developer as having "the air of a fine Daguerreotype, without any of the disadvantages arising from the reflection of light from a polished silver surface"; he proceeds: "For this beautiful result photography is indebted to Dr. Diamond, who is still pursuing the subject with much zeal." At what period Mr. Ellis proposed the protonitrate we have no means of determining; but his formula would practically have been prohibitory. It consists in adding sulphuret of iron to nitric acid, allowing the mixture to stand until the acid was saturated with iron, taking care to get rid of the sulphuretted hydrogen evolved; pouring off the liquid, filtering, boiling in a Florence flask to get rid of sulphur, and again filtering! Dr. Diamond's method, as is well known, is double decomposition with nitrate of baryta.—Ed.]

THE PROPOSED "PROGRESS" MEDAL.

DEAR SIR,—In the discussion on Tuesday evening on the subject of instituting a sort of "progress" medal for marked improvements in the science or art of photography,

I cited three instances which might possibly be taken as examples of what the council intended to do. The instances I selected were the award of a medal to M. Obernetter, for his elaboration of the powder process in multiplying negatives; to MM. Eder et Toth, for their investigations upon nitrate of lead as an intensifier; and to M. Rousselon, for his work connected with photo-gravure.

M. Warnerke met this statement by a direct contradiction, to the effect that medals were not given abroad for general progress, but only for the solution of some problem definitely set forth beforehand. As the matter was one practically outside discussion at the moment, I did not think it worth while to trouble the meeting with further remarks, but perhaps you will now permit me to affirm once more what I said. No one is better aware than myself of the practice that exists at Vienna and at Paris, to offer medals for the accomplishment of certain special work, and it is not three months ago that I myself urged M. Warnerke to claim an award, offered for the production of a supple and transparent film, by the Vienna Photographic Society. But the instances I took care to select differed from the above. No mention had been made by foreign societies of an intention to make an award for researches upon lead as an intensifier, or for a method of multiplication of negatives by the powder process, or for the special work which M. Rousselon has accomplished.—Faithfully yours, H. BADEN PRITCHARD.

Woolwich, Feb. 14th.*

WATER FOR PHOTOGRAPHY.

MY DEAR SIR,—Will you allow me, through the medium of your valuable paper, to say a few words as regards water? Water, I may say, is the staff of life—only don't, reader, think I am a teetotaler by this expression. How useful it is to all, in whatever preparation they use it! How very useful for the tea-totaller in making his tea! (perhaps he does not drink tea; our courteous Editor can, perhaps, find out for me, as I am very anxious to know) But how useful to the photographer! Without it, where should we be? Well, we should be nowhere.

But to business. Distilled water is water which has been vaporized and condensed; by this process it is freed from impurities. Pure distilled water leaves no residue on evaporation, and it remains perfectly clear on addition of nitrate of silver, even when it is exposed to light. It should also be neutral to test-paper. Rain water has undergone a natural process of distillation, but generally contains a small portion of ammonia, obtained from the atmosphere, which, of course, gives an alkaline reaction to test-paper. It is first-rate for photographic purposes if collected in clean vessels, but should not be taken from common rain tanks.

Spring or river water contains sulphate of lime and chloride of sodium in greater or less quantity. On boiling it, it is generally purified water for nitrate bath. Common hard water can often be used when nothing better is at hand. The chlorides it contains are precipitated by nitrate of silver, leaving a small quantity of nitrates (soluble) in solution which are not injurious. Ordinary spring water does for the iron developer, except for the pyro acid one, which rapidly decomposes if hard water is used. The comparatively small amount of chlorides usually found in common water does not decompose much of the free nitrate in the exposed film, hence failure in the development from that source does not arise, except to a very limited extent.—Yours, very truly,

Grafton Underwood, Kettering. O. R. P. VERNON.

P.S.—Now we are on the subject of nitrate of silver, I have a formulæ for nitrate bath which I obtained of Mr. Edwards. My time being completed, I am at liberty to give it. Words cannot speak high enough of it, but it is too long to give in this letter, therefore if any reader likes to know about, he shall have it on application.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE Annual Meeting of this Society was held on the evening of Tuesday, February 13th, Mr. J. GLAISHER, F.R.S., in the chair. The minutes of a previous meetings were read and confirmed, after which Scrutineers to examine the voting papers were appointed.

Captain ABNEY wished to state that his nomination to the office of president had been made without his knowledge or consent, and if elected he did not wish to accept the office.

The Scrutineers retired to examine the papers, and at a subsequent period of the evening made the following return:—

President.—J. Glaisher, F.R.S.

Vice-president.—Captain Abney, F.R.S.

Treasurer.—J. Spiller, F.C.S.

Council.—F. Bedford, W. Bird, J. Hughes, R. W. Thomas, H. P. Robinson, J. T. Taylor, and W. Mayland.

THE SECRETARY read the report of the Council, which was received and adopted.

THE TREASURER then read his financial statement, from which it appeared that the balance in hand amounted to £253 5s. 9½d.; the balance in favour of the Society, including assets, was £406 12s. 11½d. Referring to the falling off in the returns of the exhibition, Mr. Thomas pointed out that other exhibitions of the same year had been equally unsuccessful, and that from various causes. The political excitement was to some extent answerable, especially as it filled the daily papers, and to that course he attributed the absence of notices of the exhibition, which always affected their success.

THE CHAIRMAN, in highly eulogistic terms, proposed a vote of thanks to Mr. Thomas for his able services as treasurer, and for his energetic efforts on behalf of the Society's interests generally, to which they were indebted for the privilege of holding their meetings in that room. The motion was passed by acclamation. After an acknowledgment from Mr. Thomas,

THE CHAIRMAN proposed a vote of thanks to Mr. Friswell, their late honorary secretary, which was duly passed and acknowledged.

Captain ABNEY thought it would be for the advantage of the Society, and of the art generally, if the system were revived of giving a medal of honour to persons who should, either in connection with the art or science of photography, make the greatest step in advance. Such a course was followed by other learned societies, and he thought that such a plan provided a valuable stimulus to effort. Such a medal to be awarded by the council with, at least, a three-quarter majority.

Mr. SPILLER seconded the proposition.

Mr. KENNETT begged to support the motion.

Mr. J. R. SAWYER wanted to know, as the council would award such medal, in what manner members of the Society would gain assurance of the worth of the advance made, and the worthiness of the recipient; because he thought that the award of such a medal, to have any value should not admit of doubt or question. He apprehended it would be rather for scientific discovery, than merely for personal work produced, and would be for new ground broken, rather than for simple improvement.

Mr. H. B. PRITCHARD mentioned that such a plan was at present pursued by continental societies. The French Society recently gave a medal to Mons. Rousselon for a system of photography. In the German Society Messrs. Eder and Toth had recently received a medal; and last year M. Obernetter received a medal for the powder process.

Herr WARNERKE said that, as a rule, foreign societies gave medals for a special discovery or improvement previously announced as open to competition.

Mr. YORK thought the plan of offering a medal for a specific discovery was a good one; and might be with advantage adopted. The subject of pinholes, for instance, might well be investigated. All were familiar enough with the deposit which caused the pinholes; but no one seemed certain of its nature or constitution, or cause. He would undertake to supply the material, if the Society would have it, properly analysed.

Mr. SPILLER said he had that subject under examination to bring before the next meeting, and would be glad to accept some of the deposit from Mr. York.

Captain Abney's motion was eventually carried unanimously.

Mr. H. B. PRITCHARD then read a paper on "Photography from a Holiday-maker's Point of View." He exhibited his small camera

and dark slide, and a stand which formed a serviceable Alpine stock. He also showed some fine examples of photography produced with the slight impedimenta which could be carried during a pedestrian tour.

Herr WARNERKE, referring to the sensitive films which Mr. Pritchard had used, wished to mention a facility to the traveller which these films presented. A gentleman who had recently started for Africa had taken a stock of them and a camera. He knew nothing whatever of photography, but was instructed how to select and focus a view. A few days ago he received, from Cairo, a small post parcel, with a stamp of one piastre, equivalent, he thought, to about twopence-halfpenny. This parcel contained half a dozen film negatives for development. He had developed them, and now showed them to members.

After some further conversation, a vote of thanks to Mr. Pritchard and to Herr Warnerke was passed.

Captain ABNEY exhibited to members some examples of the instability of aniline dyes. Pieces of paper, dipped in the dyes, were cut in two, and one-half exposed to light for a month, whilst the other half was protected. Many of the tints were entirely changed.

A conversation followed on the affinity of aniline dyes for animal substances.

THE CHAIRMAN announced that at the next meeting the subject for discussion would be the silver bath, and Mr. Spiller would bring the subject before the meeting.

The proceedings then terminated.

EDINBURGH PHOTOGRAPHIC SOCIETY.

AN ordinary meeting was held in the Hall, 5, St. Andrew Square, on the evening of Wednesday, the 7th inst. There was a very large attendance, and the chair was occupied by JOHN LESSELS, Esq., President.

The minutes of the last ordinary meeting were read and approved, and the following gentlemen were admitted ordinary members: Messrs. Edwin Smithells, David Gregg, Robert R. Raeburn, M. M. Scott, H. C. Peacock, G. B. Rodger, James Abbot, Archibald Downie, J. Adamson, Andrew Pringle, Andrew Dewar, P. S. Smith, J. Forrester, J. Simpson, W. H. Cunningham, and J. Forbes.

Mr. NORMAN MACBETH, A.R.S.A., one of the judges at the late Exhibition, read a paper on "The Works of Karelina, and what may be gathered from them" (see page 74).

Mr. TUNNY congratulated Mr. Macbeth on the exceedingly interesting paper which had just been read. It showed that a very large amount of attention had been given to the works in question, and he (Mr. Tunny) thought them quite worthy of it. Karelina was a thorough master in his art, and well deserved the high recognition (the gold medal) that he had got. He could not, however, agree with Mr. Macbeth in his observations regarding art. Fine art is not a thing of paint and brushes, neither is photography an outcome of camera and lens. In both cases they are the mere tools guided and directed by a trained and cultivated brain. A true artist, whether he is the one or the other, will put his mind into his work, and stamp it with his own individuality. With reference to the prize picture, which had already been the object of considerable discussion, and puzzled not a few as to how the effects had been produced, his opinion was different from that of Mr. Macbeth. He did not think it was taken in direct sunlight, as, in that case, the shadows would have been much deeper. The light, he thought, did not come by the window that was shown in the picture, but from a point above it, and both in front and behind the curtains. On the whole, the picture was, in his opinion, not nearly so simple as Mr. Macbeth thought, and many of the lights had been put in; and some of the shadows, particularly those on the dress of the lady, were the result of sunning after printing. With a view to test his opinions on the subject, he had, a day or two ago, from memory, tried to reproduce the composition and effects in his studio, which he had arranged for the purpose, and begged to submit the result for examination to the members. With him it was not a question of how a picture was produced, but what is the character of the production, and he had no hesitation in saying that, in his opinion, after much careful study of the works in the late Exhibition, Mr. Karelina stands unrivalled and alone.

Mr. BASHFORD also complimented Mr. Macbeth highly, and said that his paper was more valuable than anything he had ever read in connection with photography. Mr. Macbeth had not only pointed out the merits of the picture, but had given the reason why it was to be admired. He had never seen so much useful information given in so small a space. He agreed with Mr. Mac-

FEBRUARY 16, 1877.]

THE PHOTOGRAPHIC

both on the whole, and especially in that, that the operator who arranges that which he wants, agreed with Mr. Macbeth in what might fairly be called the simple work of the camera. He (Mr. Macbeth) leave all defects that might be there; but that was really too far. His opinion was that the photographer should be getting as perfect a photograph as possible, and then use either the pencil or the brush, or both combined, where by such means the work can be aided or improved. He heartily thanked Mr. Macbeth for the lessons in composition, and the many lessons on other matters that he had given the members.

Mr. TURNBULL said there was undoubted evidence of much work of both pencil and brush, as well as of shading, on the prize picture; but the works of the distinguished foreigner were no doubt very grand, and everybody might learn something from them.

Mr. DAVIES said the Society was much indebted to Mr. Macbeth for the great trouble, not on this occasion only, but frequently before, in educating the members. He heartily concurred in all that had been said in favour of Mr. Kareline's works, and suggested that the picture "Blind Man's Buff" would throw some light on how the prize picture, as well as many others equally puzzling, were produced. The window in the background of the "Blind Man's Buff" picture was the other side of the window in the prize picture, and he had no doubt that it was simply a "property" that might be placed wherever it was wanted.

Mr. ASHER spoke highly in favour of Kareline's works, and took some credit to himself for having picked out his works in the Paris Exhibition of last year. On referring to his note-book he found that he had thought them the very best there. In his opinion the prize picture was an enlargement from a smaller negative.

Mr. BOW agreed with Mr. Macbeth in his admiration of Kareline's works, but not that the prize picture was the best. The portrait of Kareline himself was, he thought, finer. He thought, also, that Mr. Macbeth was wrong in condemning finish. An unskilful attempt to finish a photograph was doubtless objectionable; but when skill and finish go together, there should be no limit to it.

Mr. FAWCETT thought the prize picture had been printed from two negatives, and that there had been much retouching and shading; but both were admirably managed.

Mr. VALENTINE, of Dundee, regretted that the distance from Edinburgh prevented his giving the Exhibition as much attention as he would have liked. He could not understand why the gold medal had been given to the picture principally under discussion, and thought many of the works of the same artist were much better. He had no doubt that Kareline used reflectors very freely, especially in such compositions as that of the prize picture. Regarding the question of photography as an art, he would say that into whatever work artistic feeling was brought, that was an art; and it was well known that the feeling of the man could be and was brought into the work of the camera. Many years since, he was able to pick out the works of Mr. Rodger, of St. Andrew's, from any number of pictures by other photographers, and that simply because there was something belonging to the artist himself infused into every picture that he made.

Mr. MACBETH, in reply, said that he was sure no one would charge him with a desire to trample on anybody's toes; his only aim was to conscientiously do what was right. Photography was not really a representative art. It missed the cultivation of the eye in acquiring correct notions of form and shape. It simply realises what is presented to it, and has no aim beyond realization. Keeping this in view, however, he had no hesitation in saying that photography was a power in art; and he did not think anyone at the present time would be found to defend the stupid ignorant prejudice that some artists had at one time shown against photography.

Mr. PANTON moved a hearty vote of thanks to Mr. Macbeth, which was passed by acclamation, and said that he had bought the portrait of Kareline for the purpose of presenting it to the Society, which he now begged to do, and for which he received a vote of thanks.

The PRESIDENT laid on the table a number of very fine large views by Mr. Valentine, of Dundee, which that gentleman wished to present to the members of the exhibition committee, as a small acknowledgment for the pleasure he had derived from the result of their labours; and accorded him a vote of thanks for his liberality.

In acknowledging the vote of thanks, Mr. Valentine said that

Knowledge of Photography.—It is a pity that better observations are not made between the photographer and the public. A more ready knowledge of the art would be of great benefit to both parties.

Mr. LEBWELL said that he had seen the prize picture, and that it was a very fine work. He thought that the photographer should be getting as perfect a photograph as possible, and then use either the pencil or the brush, or both combined, where by such means the work can be aided or improved. He heartily thanked Mr. Macbeth for the lessons in composition, and the many lessons on other matters that he had given the members.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

The ordinary monthly meeting of the Association was held on Wednesday, the 7th inst., at the Museum and Library, Road, Bristol, Mr. W. W. STODDART, F.C.S., F.G.S., President, in the chair.

The minutes of the previous meeting having been read and confirmed, Dr. Thompson and Mr. Pusey, both of Bristol, were elected ordinary members of the Association.

Mr. W. W. STODDART then gave an address entitled "Notes on Photographic Chemicals, and their Adulteration" (in our next), after which a general discussion took place. The address was fully illustrated by specimens and experiments, and the meeting terminated with a cordial vote of thanks to the President for his address, proposed by Mr. H. A. H. DANIEL, and seconded by Mr. G. WEBBER.

Talk in the Studio.

COLOURED ENLARGEMENTS ON PORCELAIN.—We have been favoured by Mr. Alfred Harman with a sight of a couple of very charming portraits which he had exhibited at the late Exhibition in Edinburgh. They consisted of enlargements from small negatives, and printed on porcelain or opal glass. The photographs were manifestly finely modelled, and both delicate and rich in tone, rendering them especially suitable for the water-colour finish of the miniature painter. These were admirably painted in water colour, the delicate flesh tints of children being perfectly rendered without any trace of the heavy, opaque, black shadows too common in coloured photographs.

PHOTOGRAPHS OF THE POPE AND CARDINALS.—We learn from the Tablet: "A very large painting representing Pius IX., with all the Cardinals and chief officers of the Vatican, is about to be executed under the auspices of Mr. John Eastham, of Manchester, and his nephew Mr. George Cooper, of Hull. These gentlemen are in Rome, taking photographic likenesses of the Holy Father, the Cardinals, the Major-domo and Master of the Chamber, Monsignors Howard and Stoner, and other ecclesiastics attached to the Vatican. They will visit Paris, Vienna, New York, Dublin, and other places, to take the likenesses of living Cardinals, and from these photographs an immense picture is to be painted by Mr. Crozier Harrison. The expense will amount to many thousands of pounds. While in Rome, Messrs. Eastham and Cooper have taken photographs of the paintings in San Clemente, and of some of the portraits in the English College. They have also photographed the rector and students of the English College, and of the American and other colleges in Rome. They have

obtained also the autographs of the Pope, the Cardinals, and many distinguished persons. They have photographed Sir A. Paget and the officials of the British Embassy, in Rome." Another issue of the same paper says:—"On Friday, the 26th of January, the Holy Father sat for his portrait to Mr. Eastham, of Manchester, and Mr. George Cooper, of Hull, the photographer to the Prince of Wales. The negatives were taken in the Pope's private library, in presence of Cardinal Monaco La Valletta, Mgr. Ricci, and other members of the Court. Usually great difficulty is experienced by photographers when taking the portraits of gentlemen aged over seventy. The Pope, however, although aged eighty-five years, remained perfectly steady for more than sixty seconds in the positions assigned him by the photographers. He showed not the slightest weakness of nerve or unsteadiness of muscle during the sitting."

PHOTOGRAPHIC JOKE IN CONNECTION WITH THE CONFERENCE.—The *Standard* Correspondent says that the representatives of the Powers went the other day to the studio of Abdullah to be photographed in a group. When they were posed, the operator said to them, in French, "Don't move, gentlemen, don't move." "Parbleu!" said the Count de Chaudordy, "you may say that to the general, but the rest of us are quiet enough, I assure you." Some minutes elapsed before the countenances of the delegates were sufficiently composed for the photograph to be taken. The Italian residents say of the Plenipotentiaries:—

"Sono arrivati come leoni,
Partono come cagnoli."

Among the English it has been proposed that a prayer should be put up in the English churches "for some persons who are at sea." And when, the other day, some one expressed a wish that before their departure the representatives of the Powers would lay their heads together for the purpose of obtaining a better pavement for the Grand Rue of Paris, the immediate reply was that a wooden pavement would not be suitable.

AN OPERATOR'S SALARY.—Jules Guggenbeim, described as a photographer of High Street, was summoned by Henry Fensland, an operator, who had been in his employ, for non-payment of £2 12s. balance of wages. The summons stated that defendant had employed complainant on the 6th of December at a weekly wage of £2. On January 20th complainant left him. During that time he received £11 on account, leaving the balance claimed. Defendant pleaded that complainant had never fulfilled the engagement, which he did not deny having entered into with him. Complainant deposed that he entered the service of defendant on the 6th of December last. He produced the letter requesting him to come a month on trial as operator, at a wage of £2 per week. On the first Saturday after he came he received his wages for the three days, and his expenses. On the following week witness was paid £1 10s., defendant saying that he had not enough money by him to pay the whole. On the following week £1 was paid him, and the next week 15s., the same excuse being given. This system continued till he left defendant's service, when the total balance owing to him was £2 12s. He had never heard any complaint as to the manner in which he did his work. Defendant declared that complainant was not able to do his work, and that on the last day he agreed to come on the following week at half price, but he did not do so. Complainant admitted having made this agreement, but stated that he was engaged as an operator, and the work complained of, which defendant alleged he was unable to execute, was new work, altogether apart from the duties of an operator. Notwithstanding this fact, he entered into the agreement, which he afterwards refused to carry out, acting on the advice of his father. Defendant alleged that he complained daily of the manner in which complainant executed his work, and also of a number of articles which were broken, as he believed, by defendant. These articles included five or six glass tunnels, a focussing glass, worth 25s., and a host of other articles; in fact, it was "break, break; broke, broke." Complainant denied breaking the tunnels, and also stated that the focussing glass was in a proper condition when he left defendant's employ. Defendant here asked complainant whether he did not tell the servant girl, in a dark room, that there was no God nor devil in this world; but the question was ruled to be irrelevant. Complainant further stated that directly he left his situation

he received an insolent message from defendant, to the effect that a quantity of chemicals were missing. The Bench expressed regret that defendant had been so foolish as to put himself to all this expense. Complainant had earned his money, and must be paid, and he would leave the court with a character unimpaired. Defendant was ordered to pay the amount, and also the costs.—*Oxford Times*.

DALLASTYPE.—the *Paper and Printing Trades Journal* states that "The *Journal für Buchdruckerkunst* attributes to Preuss the photo galvanic process known as Dallastype. It published 20 years ago photo-electrotypes on engravings prepared by Preuss."

To Correspondents.

R. LAMBERT.—Mixing preparations of oxalic acid, or chloride of lime, in the same room where a vessel containing a solution of nitrate of silver was standing, ought not injuriously to affect the latter. Any contamination caused by the fumes of chlorine would be manifest in the form of chloride of silver, which would have been visible to the eye.

BACON.—As a rule, the price of nitrate of silver is without change and fluctuation is not a normal thing. We cannot tell the reason for its recent sudden rise to 3s. 11d. per ounce. Indeed, we were not aware of the fact. It certainly seems, as you suggest, another illustration of the instability of silver!

J. S. C.—The registration of a photograph is effected at Stationers' Hall by giving, on a form prescribed for the purpose, a description of the picture, with the name of the owner of the copyright, &c., and the payment of one shilling. The form can be obtained at Stationers' Hall for one penny, by personal application, but no business is done there by correspondence. To meet this difficulty for country readers, our Publisher will attend to the matter if you forward him particulars and eightpence in stamps. 2. There is a little smoke produced by the combustion of the mixture you mention.

ENQUIRER.—The kind of background necessary in a studio depends much upon the taste of the portraitist. Two plain ones of grey, dark and light, are all that are necessary; but various others may be used with advantage. For vignettes a light background is necessary. 2. The grained texture to which you refer is produced by double printing, a second negative with a suitable grain being used after the portrait is printed. The grained negative may be obtained by photographing a piece of rough drawing paper, or a piece of Turkey morocco leather. 3. We prefer white blinds. 4. We cannot recommend any special lenses by name in this column. You will find details in our advertising columns; or if you send a list with a number or letter attached to each, we can then indicate which is best suited for your purpose.

X. Y. Z.—We do not see any advantage in permanently blocking out any light. We should obstruct it where it was not required. 2. The curtain we should prefer with rings, to slide on a rod. 3. Bigelow's system seems well adapted for readily securing varied effects in lighting.

H. PARSONS.—The Secretary to the English Commissioners of the Paris Exhibition of 1876 is, we believe, Mr. Cunliffe Owen. We have not seen any announcement of the offices of the English Commissioners yet; but a letter addressed to Mr. Cunliffe Owen, at the South Kensington Museum, would probably reach him.

W. B.—We have no doubt that most of the professional enlarger will produce you work on rough drawing paper, which will permit finishing in crayons.

J. L. S.—M. Constant died early in the summer of last year. In him photography lost a valuable and careful experimentalist, and we lost an esteemed friend and contributor.

KINGSTON.—The dry plates you mention do not require a long exposure. try two or three times as long as for wet plates. You will find full instructions for alkaline development, which they require, in our YEAR-BOOK just issued, on page 126. By managing the development you can correct over-exposure if the plate show symptoms of the exposure having been longer than necessary.

B. L. D.—There can be no legitimate doubt that a good carbon print is permanent. The facts which you mention to the contrary are not evidence of any want of permanency; they simply show that such a picture is not indestructible. The best picture of any kind which can be produced can be destroyed if subjected to unfair conditions. An oil painting or an enamel can be destroyed. An oil painting would blister if placed for months in hot sunshine. We cannot precisely define for you what is included in the respective licenses granted by the Autotype Company; but they will doubtless do so if you apply to them.

Several Correspondents in our next.

The Photographic News, February 23, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHY VERSUS ENGRAVING.—THE SCIENTIFIC KNOWLEDGE OF PHOTOGRAPHERS.—HOW TO MAKE SHELLAC VARNISH.

Photography versus Engraving.—When will painters in this country begin fully to understand the advantages photography has conferred upon them? In France and Germany artists have been for some time past alive to their interests by employing the camera, instead of the engraver, to copy their paintings; but here in Great Britain it was but the other day that leave was obtained to photograph and publish some of the paintings in the Royal Academy. British painters allow themselves to be plagued by pirates, and are for ever proceeding against those who get money by surreptitiously copying their works; yet it seems, so far, never to have occurred to painters in England to take the matter into their own hands, and make profits for themselves. In Berlin, as also in that headquarter for art, Munich, very large sums are paid for photographs—*a silver even*—of paintings; thirty and forty shillings being no unusual price to ask for large unmounted copies of paintings. The firm of Goupil et Cie., of Amsterdam, which employs (for its smaller work, at any rate) the Woodburytype process, or, as it is there termed, the photoglyptique method, also does a most extensive business in copying artists' pictures, and selling the prints at a high figure. Twenty and thirty francs is a common figure for twelve and fifteen inch pictures by good painters, and when it is borne in mind how little such copies cost to print and produce, it is evident a large surplus remains for the artist or owner of the copyright. A twelve-inch photograph mounted cannot cost more than a few pence to produce, and therefore the public are asked thirty or forty times the outlay that is made. It is only the other day that we saw in London a photograph of this size—framed, it is true, but very simply indeed—marked at thirty shillings, and we have reason to believe that a large number of such pictures are sold. It was one of Goupil's reproductions, and the work of a modern French artist. If we set the latter's royalty at ten shillings—and it is probably more, than less—an edition of four or five hundred would realize a couple of hundred pounds, while there is no reason why, with agents at the various capitals, a popular picture might not be sold in some thousands. There is no costly outlay for engraving, and if the tints are only suitable for photography, a far truer reflection of the artist's original work is presented if photography is employed in its vulgarisation. Gentlemen interested in art, after a visit to the French or German capitals, generally come back now-a-days with a glaring account of foreign photography, and declare that in Great Britain there are none to compare with the photographers abroad in regard to the skill and intelligence employed in copying pictures. Visitors will bring back with them a dozen such photographic sketches, because there is nothing of the kind to be purchased in this country. In this, however, like most hasty people, they mistake cause for effect. Our photographs would be quite as clear as their foreign brethren in such work if they only had it to do. The most successful by far of all who have tried their hands at the delicate operation of copying paintings by photography was Mr. Bingham, who went over to Paris simply because there was no work of the kind for him to do in England; and his firm is, we believe, still the most noted in the French capital for producing prints of this nature. By reason of the large amount of work done in this way at Paris, Berlin, Vienna, Munich, &c., there cannot be a doubt that it must be lucrative to the artists, and for this reason we commend British artists to tarry no longer, but to follow the example of their other brethren in Europe. It is only a very fine picture indeed that will bear the cost of engraving, but any happy sketch might be photographed to the profit of its author, who would not only gain money, but reputation too, by the copying of his work.

The Scientific Knowledge of Photographers.—It is a pity photographers are not better chemists; they would then be able to discern much better between profitable and unprofitable investigations. Many a weary hour or day is spent in trying to bring about certain changes, which a more ready knowledge of chemistry would have shown them could be effected in the simplest manner, or have told them was, perhaps, impossible. Many who are thus ignorant have very curious ideas about analysis. If they want to know all about a thing, it is only necessary, they imagine, to ask a chemist to go through the form of "analysing," and it is done. You put the substance, as it were, into a machine, turn the handle, and the products fall down through the outlet pipe. Nothing is too abstruse to get at. You must inevitably find out all about a thing directly you analyse it. We remember, some years ago, a gentleman in a great state of mind rising at one of the meetings of the Photographic Society, and, with a display of temper, telling the members that it was really pitiable photographers did not, as yet, know how silver prints could be produced of a permanent character. "For goodness' sake, let us have a commission, and find out how to secure durable silver prints," said he, "if we do not know the way to do so at present!" It only wanted a commission to do it, he thought, and then the whole vexatious business would be at an end, at once and for ever. He would have treated the moon in the same way, probably, and asked to have that analysed if it had worried him. Indeed, there is nothing that a chemist cannot do, in the opinion of some people. The scientific man has only to be employed upon a problem, and it is solved that instant. They don't know how he goes about it, nor do they wish to be informed, for they prefer the whole matter to be shrouded in mystery. They can then believe in it, heart and soul. They don't understand such things, they tell you, and they cannot begin now. When people talk like this, we always think of a popular definition of science we once heard. Science, to the general public, is anything you can't comprehend; directly you begin to understand it, it ceases to be science. So it is with the photographers to whom we allude, and some—even of the cleverest—would be as much taken aback to learn that they are really acquainted with a good deal of elementary science, and have to bring scientific principles to bear whenever their bath, or developer, or printing goes wrong, as the *Bourgeois Gentilhomme* was, when he was told that he had been speaking prose all his life.

How to Make Shellac Varnish.—Some experiments have recently been made by M. Pelts on dissolving shellac in alcohol. The reason why a turbid liquid is usually the result is because the shellac contains about four per cent. of fatty ink, or any substance which remains in suspension. M. Pelts suggests the addition to the solution of powdered chalk, for in this way a liquid is secured which is three-fourths clear, whilst the lower portion can be rapidly filtered. If prepared on a large scale, the shellac varnish thus prepared may be filtered through felt. Another method of preparing shellac solution is to add to it, for every three parts of solution, one part of petroleum-ether. In this way two layers of solution are secured, the upper and lighter coloured layer containing the petroleum-ether with the wax dissolved in it. Instead of petroleum-ether, ordinary benzole may be employed, when the same results will be furnished.

M. LAMBERT'S INSTRUCTIONS FOR CARBON PRINTING.

In the midst of the discussions which were raised as to the claims of M. Lambert in connection with the processes associated with his name, for the most part the subject of patent protection, no question was ever raised as to the great skill and capacity of M. Lambert personally, or that his mode of working the carbon process was singularly successful and satisfactory in result. Whilst he protected

his improvements by the aid of the patent law, he was no monopolist of his knowledge gained by experience. One of our American contemporaries who is in antagonism with Mr. Lambert recently published his instructions to pupils and licensees, and for the benefit of the general reader. M. Lambert, referring to this publication, endorsed the instructions as quite correctly given. The patented processes are of course only available to licensees; but much of his experience will be found of value to all carbon experimentalists. We shall therefore make some extracts from these instructions. Here are his instructions for carbon manipulation in producing what he terms *chromotypes*.

"Sensitize the purple chromotype tissue in a solution of bichromate of potash, half an ounce to fifteen ounces of water, with five drops of ammonia to the pint; but in hot weather use a weaker solution and less ammonia. In very hot days put ice in or under your bath, and dry the tissue in a cold draught; and as soon as dry enough not to be tacky, roll the tissue and put it in a tin box. Sensitize for two minutes in summer and three minutes in winter. Use the Lambert photometer to print portraits and transparencies, and the actinometer to print the borders.

"We find, on visiting our licensees' studios, that there are here a great variety of bichromate of potash, all having different strength. With the majority of them $1\frac{1}{2}$ to 2 ounces B. P. to 100 ounces of water works the best. We advise you to try different baths of different strength with the bichromate of potash you use, and adopt the best adapted to your negatives. *Too strong a bath will give you reticulations, whilst a bath too weak will give you no half-tones.* A strong bath is better adapted for strong negatives, and a weak bath is preferable to print from weak negatives.

"If your tissue is too soluble, thus losing half tones in development, which is too rapid, sensitize a few days before using, keeping the tissue in tin box. The more ammonia you put in your sensitizing bath the quicker the printing, but slower the development. If the tissue is dried too quick, it is more soluble; if dried too slow, it is more insoluble. We advise you to heat your room where you dry the tissue, if it is either damp or cold; a current of air is very good to dry the tissue.

"Prepare your opal or plain glass by rubbing on it a solution of five grains of wax to the ounce of benzole; then take off the excess by rubbing with flannel, and polish with a clean flannel. Collodionize with collodion (ether six ounces, alcohol six ounces, and one drachm of pyroxyline). As soon as evaporated, immerse in water until the water runs evenly on it. These plates can be kept in water any length of time. Place the pieces of tissue, after immersion in cold water, on the plates thus prepared; after throwing a little water on, cover with the india-rubber cloth, squeegee, and put under pressure between blotting-paper for about ten minutes. Squeegee smoothly at first, then heavily, taking care not to stop or begin on the print.

"Develop in a flat dish. When you see the powder dissolving on the edges, pull the paper off, taking care not to touch the collodion; then put in a perpendicular grooved bath, at a temperature of from 85° to 100° Fahr. It is advisable, after development, to immerse in alum water (water two quarts, alum a handful) to render the gelatine insoluble. Wash, dry, and then spread on the transfer paper previously soaked in warm water. While yet damp mount on cardboard with starch paste, and as soon as dry pull off from the glass and cut them ready to deliver. We do not recommend this method of mounting unless a very bright gloss is required.

"The best way to mount the prints is to lift them up from the glass, when dry, under water. Cut them, and mount with starch as for silver prints; then burnish. This is the easiest way, and gives a finer gloss.

TRANSPARENCIES, ETC.

"Albumenize (as for negatives) instead of waxing your plates for transparencies, then collodionize; the prints will stick better to the glass.

"Do not float, but immerse, the tissue in the sensitizing bath from two to three minutes. As soon as you see the edges of the tissue turn up, it is well sensitized. Pass a very fine sponge on the face of the tissue so as to prevent air-bubbles, and rub off the whitish powder of paper usually adhering to it.

"When the paper is hard and rolled, roll it from one end to the other, under the solution, and *vice versa*, so that the solution touches every part of the tissue, until it gets flat. Never touch sensitized paper when dry, or it will produce stains; never touch, neither, the face of any unsensitized tissue when dry.

"Never use the same sensitizing solution over two or three times. The tissue when wet is not sensitive, so fear no light. Dry your tissue, if possible, in a room not too warm and not too damp, as it must not be damp or horny when used. A room where there is no draught is the best adapted to dry the paper. The drier the paper, the less sensitive: the damper, the more sensitive; but when wet, it is not sensitive at all.

"Only sensitize the paper a few days before being used, as after a time sensitized paper is neither quite so soluble nor so sensitive, and requires a little longer exposure and development in hot and dry days; but in winter and damp weather it is the contrary, the paper becoming more sensitive on account of the dampness of the air, but in winter you can use paper one week to twelve days old. Place a glass rod on the front edge of the sensitizing dish, over which draw the surface and back of the tissue upon removal from the liquid, to take off all excesses, and have an even surface. Always use pure yellow bees'-wax, not the prepared white kind sold by chemists.

"After coating your plate, rub repeatedly (first on the length, then on the breadth of the glass) with a tuft of papier Joseph (better from being used a few times; other substances, in absorbing the wax, will make the prints stick to the glass) until the benzole is completely evaporated, which you will perceive by feeling a resistance. No other pressure than the weight of the arm must be used with the papier Joseph, which can be used indefinitely. Then take off the excess of wax by rubbing heavily with a piece of flannel (which you can use indefinitely), and then polish with a clean piece of flannel, which you keep for that purpose. If the plate is properly waxed, it will have, by reflection, a veiled appearance, and if rubbed with the finger will give a resistance and grating noise. In very hot days do not rub too hard with flannel, as the wax, being soft, might come off. Should the operation not be done properly, you will meet with the following accidents:—The print will not adhere to the glass if the excess of wax has not properly been taken off with flannel; the print will stick to the glass if not enough wax has been put on it, or if too much has been rubbed off.

"After collodionizing the glasses (any good plain collodion will do), let them dry for about three minutes; then put them in cold water until there are no greasy lines seen on them. In cold weather, do not use the water too cold, as the film would have a tendency to peel off. Always use faultless glass, and in preference pot-metal opal glass. Roughen the edges of these glasses, or the collodion might slip off from them in washing. If you use common glass instead of opal, the collodion film might slip from the plate when placed in water, unless the edges have been well roughened.

(To be continued.)

MR. KARELINE'S WORKS, AND WHAT MAY BE GATHERED FROM THEM.

BY NORMAN MACBETH, A.R.S.A.*

ALTHOUGH the photographer can never lay claim to any merit in the formative part of his work by drawing, and certain other high departments of fine art, which are a

necessary concomitant of the painter, who has to represent his own individual impressions of character—to invent a style and produce qualities of texture and colour unlike nature in fact, and at the same time be charmingly like in appearance (some comparisons are odious, and such work as we have now indicated should never enter into comparison with photographic work proper, which, in that department, has no art in it, being purely a reflection through the lens), yet who does not see what a boon it is, to every student of art as well as of nature, to have in our hands such perfect translation of facts as we have had presented to our notice so recently? However, there are corruptions in every art, and nothing is so much to be deplored in photography as the now too common habit of working on the negative, destroying surfaces, and thereby losing all that is so real and authentic.

I fear, however, it is hopeless to expect any renunciation of working on the negative so long as the development of the highest lights, and in particular of skin, is not better manifested than it is at present. It is in the department of light and half-light (the latter being the region of colour) where the development comes most short.

I have no objection to any amount of skill or art being rendered on a positive, if people will prefer them, but let them be classed as what they really become—photographic art-miniatures. I maintain that it shows a weakness in the photographer when he has recourse to this practice with a view to make up deficiencies which both he and the public are fully conscious of. It is the apparent absence of this in Mr. Kareline's work which forces me to acknowledge the superiority of his productions, fully demonstrating that the faintest light lying in the deepest shade may be secured, while, at the same time, the highest lights, even in sunlight, are kept free from solarization, and are consequently vigorous.

I should like to have dwelt longer on this topic, as one of the things in particular from which we may gather much, as expounded by the works of Mr. Kareline. Suffice it to say that the danger into which many photographers run appears to me to be the notion that strong relief is of the highest and only excellence; and, either unconsciously or through inexperience, the tendency, by modelling on the negative, is to go to excess with it, changing the natural moisture of the skin into the appearance of the sitter's face having been oiled, or producing the appearance of a white porcelain surface, giving no representation of the individual's complexion.

It is a complete fallacy to suppose that such work, seeing that at its best it is but mongrel in character, will ever attain to be classed as high art. Fine it is, if mere minuteness be considered of the right kind. It is not in that sense, however, that fine art is to be considered, for in painting—as a representative art—mere fineness is not regarded as good art, but rather otherwise—as poor and vulgar; and, on the other hand, roughness, the other extreme, is not regarded as of itself an excellence. It is the amount of truth which is imagined by surface-rendering, and the extent to which it is suggestive, which constitutes the excellence of such manipulation; and if that be difficult in large work with the painter, how much more difficult and precarious must it be for the photographer, who attempts such expressive work on surfaces much more minute! Photographic work in itself is not representative: it is the most positively realistic manifestation of a pure reflection, and should infallibly present nothing beyond what is before the instrument, except what may be treated by light on the positive. It will take some time before the public will see the importance and force of this; but it is the duty of every photographer to pursue the most legitimate methods of production which are in strict accordance with its own scientific bearing; for, rest assured, the more perfect a transcript of nature can be made through photography—i.e., by light and chemical development, without extraneous aid—the

more will it be confided in as an auxiliary to art, and be highly prized under any circumstances, but more especially when parties who have been photographed shall have ceased to live.

Having thus analyzed and pointed out the merits of Mr. Kareline's prize work, I shall now rapidly glance at some of the rest of his works, differing from this in character. Mr. Kareline forwarded above twenty separate frames, besides two portfolios containing smaller works, all giving full scope of judging his general capabilities as a photographer. His "Portrait of Platonoff" (No. 776) is, perhaps, the best specimen of portraiture proper which he has sent to the Exhibition. The subject is not placed in sunlight. The white dress is managed with much breadth of effect, the position is simple but vigorous in action, the character strong and well sustained, and the tone of the flesh (especially in the arms) is finely realised, and that, I have no doubt, through much judgment. This, of all his works, is the least photographic in appearance. The accessories are very simple, and the aspect of the portrait is altogether not unlike those by Sir Joshua Reynolds.

I have already made reference to Mr. Kareline's own portrait (No. 800). It was taken in the open air, in sunlight. He is standing with a sketch-book in hand, looking for an idea. He has on a black felt hat, which casts a broad shadow over the face. A plaid over the right shoulder is relieved by the shadow of some dark space, like a door, while the black hat is relieved by a wall of broken plaster in sunlight. I should have liked this head to have been a little farther up in the light, preventing the lateral line of the door from affecting the repose of the head. This is one of the things which I humbly think Mr. Kareline should guard against, for apparently in several of his works extraneous objects of no important bearing on the subject are permitted to molest much beauty. For instance, in a place in one of his pictures, where a party play at blindman's buff, the elegance of design in the figures which compose the group is completely marred by the framework of screens and windows in the background, constituting lines at right angles to each other.

I find these defects in several of his works, which are very painful to the eye. There is one cabinet portrait (No. 498) in which the gentleman is seated at a table running parallel to the base, and at right angles to the side of the picture, without being softened or counteracted by objects lying more or less acute. This portrait of himself is, apart from the objection of which I have been speaking, a fine specimen of the kind of work which I imagine Mr. Kareline will yet do wonders in; and I would strongly recommend him to pursue this walk as unquestionably that wherein his strength lies. This picture is certainly the finest illustration of his power in development. The completeness of forms in shadow are very admirable, showing Mr. Kareline equally master of shadow as well as of light.

Before closing, I must call attention to Mr. Kareline's cabinet portraits. They are very excellent in the realisation of many of the qualities to which we have alluded, such as still life; but his employment and treatment of such, and the extent to which he does so in this department of portraiture, is what I would take most exception to. I think there is too much attempted. Of course the figures in every case are well arranged, full of purpose, and completely developed; but there is a profusion of ornament and furniture which, although common to cabinet works, yet (such as is here employed) to a degree swamps and absorbs all human interest by their attractive forms, and in some instances by their light and spotted appearance is apt to give the whole work a very meretricious look.

Apart from this, some of Mr. Kareline's cabinet portraits are very fine, as I have said, both in arrangement and feeling, and it is a wonder that seldom or ever do we see anything in them like defective and imperfect sitting,

which all the more presses upon me the conviction that they are very short in exposure. His finest cabinet portrait, I think, was the Portrait of Mrs Kistkoff (No. 242). The ladylike character of this subject is beautifully worked out. The accessories in the picture are much quieter, and the never-failing mirror again successfully produces the lady in profile. If I might make a suggestion, I would recommend Mr. Kareline to make a complete change in his ornaments and furniture, because however varied they may be treated in arrangement, yet eventually these objects always cropping up will cease to charm, and become very stale. I think there is nothing like the adaptation of accessories belonging to the individual who sits for his portrait, if we could only get the use of them, but this is not always convenient.

I close by remarking that the lady's dress in this cabinet portrait is the most perfect development of a light dress which I have seen, and the tone of the picture throughout, I am certain, will not easily, if ever, be excelled in black and white.

THEORY OF THE HORIZONTAL PHOTO-HELIOGRAPH, INCLUDING ITS APPLICATION TO THE DETERMINATION OF THE SOLAR PARALLAX BY MEANS OF TRANSITS OF VENUS.

BY PROFESSOR WILLIAM HARKNESS, U.S. NAVY.*

THE term "Horizontal Photo-heliograph" is used to designate that form of photo-heliograph which, it is believed, was first employed by the late Professor Winlock, and which consists essentially of a fixed telescope, whose optical axis is accurately horizontal and in the meridian, and whose objective is directed towards the same side of the zenith as the elevated pole; the sun's rays being reflected into the telescope by a suitable heliostat. The sensitive plate for the reception of the photographic image is, of course, situated at the chemical focus of the telescope, the plane of the plate being perpendicular to, and its centre coinciding with, the optical axis of the telescope.

The heliostat mirror consists of a piece of highly-polished (but unsilvered) glass, whose two surfaces make an angle of about sixty minutes with each other. The front surface is worked as truly plane as possible, and serves to reflect the solar rays through the object-glass to the photographic plate. In working the back surface, no particular pains are taken; and, on account of its inclination to the front surface, any light reflected from it is thrown entirely away from the photographic plate. The object-glass is corrected for the chemical, and not for the visual rays. The distance between the object-glass and mirror is made as small as possible, consistently with keeping the latter clear of the shadow of the former. The sensitive surface of the photographic plate faces the object-glass, while the rays from the sun are reflected by the mirror through the object-glass, and after traversing the reticule they form an image upon the photographic plate.

The reticule consists of a system of squares formed by the intersection of two systems of very fine straight lines, which are drawn upon one side of, and respectively parallel to, the edges of a thin square plate of plano-parallel glass. In each of these linear systems the number of lines is odd, and the middle line is drawn through the centre of the plate. This reticule is fixed with its ruled surface toward, parallel to, and two or three millimeters distant from, the sensitive surface of the photographic plate. Moreover, one of the two systems of lines is set as nearly as possible vertical, and its inclination is accurately determined; and, to render assurance doubly sure, a plumb-line, consisting of a silver wire about 0.05 of a millimeter in diameter, is suspended between the reticule and the photographic plate, in

such a position that it may hang freely, and at the same time be very nearly in the vertical plane passing through the centres of the reticule and object-glass. As the light from the object-glass traverses the reticule before it reaches the photographic plate, the shadow, both of the reticule and of the plumb-line, is impressed upon every picture taken with the apparatus; and thus three different ends are gained: first, by comparing the squares of the reticule with the corresponding ones upon the picture, everything relating to the shrinkage of the collodion can be determined; secondly, the impression of the plumb-line, and also that of the vertical lines, furnishes upon each picture a fixed direction from which to measure angles of position; and, thirdly, the intersection of the middle vertical with the middle horizontal line furnishes a fixed point, which in the paper is designated as the centre of the plate. To determine the zenith distance and azimuth of this point, it is necessary to measure the zenith distance and azimuth of the corresponding point of the reticule, as seen from the second principal point of the object-glass. For that purpose, the mirror is temporarily removed, and a transit instrument is set up in front of the object-glass in prolongation of its axis. The object-glass thus becomes a collimator to the transit instrument, through the eyepiece of which the lines of the reticule may be observed as if they were at an infinite distance. It should be remarked, however, that as the reticule is slightly inside the visual focus of the object-glass, it is not generally possible to obtain perfectly distinct vision of its lines and of the wires of the transit at the same time. This difficulty is obviated by marking the intersection of the middle vertical and middle horizontal lines of the reticule in such a distinct manner that the slight maladjustment of focus does not prevent it from being seen. Then, by means of the transit, the reticule is adjusted so that the point in question is very approximately in the meridian, and at a zenith distance of ninety degrees. Finally, the exact azimuth and zenith distance of the point are measured.

The remainder of Professor Harkness's paper, which will probably be given *in extenso* in the *Memoirs* of the Society, is occupied with a full and detailed explanation, with diagrams, of the principle of the instrument, and of the models of measurement of the photographs.

NOTES ON PHOTOGRAPHIC CHEMICALS, AND THEIR ADULTERATION.

BY W. W. STODDART, F.C.S., ETC.*

THE following notes arose from some anomalous results that had been observed by the author of the paper while making some photographic experiments. It seems probable that chemical purity alone, however important, is not all that is actually necessary for the highest state of photographic manipulation. The purity of the different reagents is of the utmost importance to the chemist, but is even more so to the photographer. Sometimes the latter finds a difference in the working of baths and solutions, that chemistry alone cannot explain, and very often remains a mystery. The object was to show to the Society that physical properties have to be remembered, as well as the chemical. Most, if not all, crystals (especially when in a state of fine division) are affected by every ray of light having actinic power that falls upon them, a fact that is not often sufficiently alluded to in manuals and other works on photographic science. To prove that this curious fact is not mere theory, Mr. Stoddart exhibited several experiments, the most striking of which was the exposure of five or six simple substances to the light of magnesium ribbon. After an interval of a few seconds the room was darkened.

* Communicated by the Astronomer-Royal to the Royal Astronomical Society.

* Read before the Bristol and West of England Amateur Photographic Association.

On opening the box, the different substances were seen in an intense state of vibration, so rapid as to give forth a vivid light, having different colour according to the rate and power of the waves. On examination it was found that only the external particles, or those in direct opposition to the magnesium light, were affected. When they were removed the underlying particles were perfectly quiescent and dark. The light evolved in this remarkable manner continued for a considerable time, and was so bright that it could be seen all over the room.

Experiments were next described, pointing out what portion of the spectrum contained the greatest quantity of actinism, and also proving its presence in the invisible rays by reducing their rate of vibration, and so rendering them appreciable by the human eye.

The speaker then exhibited some samples of reagents that had been sent to him for analysis, and fully explained the most simple methods of ascertaining their purity or impurity. The first was some distilled water that had been purchased that morning. It was found to be free from all solids—as sulphates, nitrates, carbonates, and chlorides—but contained a large proportion of ammonia, which, being volatile, had passed over with the condensed steam. This was instantly detected by Nessler's delicate test, which showed by the colouration that a considerable quantity of ammonia was present. The necessity was thus shown of throwing away the first portion of the distillate that comes over, and which of course contains those things in the original water that are volatile. It may be that the presence of ammonia would account for many of those unaccountable occurrences before alluded to. It cannot be detected by the smell or taste, on account of the comparatively small amount; yet the reaction was so strong as to cause a great disturbance on the Nessler, although the quantity in the sample present did not exceed two or three parts in every million.

Some samples of glacial acetic acid were shown to contain traces of lead, copper, sulphuric, hydrochloric, and sulphurous acid. In one was manifested an empyreumatic tarry matter, that separated when neutralized with ammonia. The sulphurous acid was detected by the evolution of nascent hydrogen, a very pretty, although well-known method. To some of the acetic acid was added some pure hydrochloric acid and a little zinc. In the mouth of the glass flask was placed some moistened lead test-paper. The sulphurous acid present was decomposed into sulphuretted hydrogen, which announced itself by discolouring the lead paper.

A sample of gallic acid was shown by means of a solution of gelatine to contain a trace of tannic acid. An apparently pure specimen of nitrate of silver was placed upon the table that was adulterated with saltpetre to the extent of ten per cent. The only correct mode of testing the nitrate is by quantitative analysis, and thereby ascertaining the amount of oxide of silver.

Iodide of zinc in iodide of cadmium, and iodate in iodide of potassium, are not uncommon. A Continental sample of the latter was exhibited. The impurity is easily detected by a little tartaric acid and starch solution. If any iodide be present, it is quickly detected by the development of the well-known blue colour.

A quantity of hyposulphite of soda was examined, and proved to be mixed with sulphate.

THE IODIZING OF COLLODION WITH ANILINE SALTS.

BY MM. EDER AND TOTH.*

THE idea to employ organic iodides and bromides for sensitizing negative collodion is already an old one. Von

Monckhoven was the most fortunate experimenter in this direction, that gentleman recommending the employment of iodide and bromide of ethylamine for the purpose. The observation that iodide of ammonium forms, on mixture with alcohol, iodide of ethylamine after the action has continued some time, and that, therefore, a collodion treated with this salt has all the qualities of a ripe material, supported this recommendation of Monckhoven. The production of iodide of ethylamine is, however, connected with many difficulties, and altogether its introduction into practical use is hardly to be wondered at. This interesting result, however, which the alcoholamines of the series of fatty acids furnished as iodizing salts, caused us to undertake an investigation with the amines of the benzole series.

We chose aniline, the prototype of the above mentioned series, as the starting point of our research; it possesses, as its salts do in a much less degree, the quality of being able to absorb bromine and iodine. Hydro-iodide and hydro-bromate of aniline was produced by taking sulphate of aniline (three parts), and iodide of potassium (three parts), and bromide of potassium (two parts), and dissolving them in as little water as possible, and adding alcohol to the solution. The filtrate of crystalline precipitate (salt-petre) yielded, after evaporation on a water bath, long and only slightly tinted needles of the aniline salt.

With these we prepared two collodions:—1. One iodized by mixing a solution of 4.0 grammes of hydro-iodate of aniline in 50 grammes of alcohol with twice its volume of normal collodion, which had been prepared with two per cent. of pyroxiline. 2. A second, bromo-iodized, by means of a solution of 3.4 grammes of hydro-iodate, and 0.5 grammes of hydro-bromate of aniline in 50 grammes of alcohol.

The collodions became strongly coloured, after mixing, of a golden-yellow tint, and they contained the same proportion of iodine and bromine as an ordinary negative collodion. Both of them, however, gave unfavourable results. The films, when sensitized in a ten per cent. silver bath, were uniform enough in character, but yielded thin and very flat pictures. The exposure necessary was, all things considered, longer than in the case of ordinary collodion. As was fully to be expected from the decomposable character of aniline compounds, the aniline collodions were prone to rapid decomposition, and in the course of two or three weeks they became of a deep red colour.

We communicate these results, unfruitful as they apparently are, because they add to our knowledge of collodion and iodizers.

SELLING ALLEGED INDECENT PHOTOGRAPHS.—A few days ago, at Southwark, Louis Flowers, 18, a German Jew, was charged by the police with selling photographs of an indecent nature in the New Cut, Lambeth. William Melville, 226 L, said he was on duty in the New Cut on the previous afternoon, when he saw the prisoner go up to a gentleman, take some photographs from his pocket, and offer them for sale. From what the gentleman told him he went up to the prisoner and took from him several photographs which he considered to be indecent. The prisoner then went to a barrow on which he had many others of a less indecent nature. Mr. Safford, the Chief Clerk, said that these photographs were similar to some seized by the police on the same spot about two years ago. It was shown that they were copies of French pictures exposed in the Galleries. Mr. Partridge was of opinion that some of those first seized by the constable, and which the prisoner had offered for sale, were very indecent, but still he did not think that they came within the meaning of the Act of Parliament. He required the prisoner, however, to enter into his recognisances to come up for judgment when called upon, and directed the police to keep possession of the photographs. Inspector Whiting, L Division, who had them in his charge, shortly announced that the prisoner had consented to have them destroyed. Mr. Partridge requested the inspector to see that they were.

VIOLET LIGHT FOR STUDIOS.

A FEW weeks ago, referring to M. Scottelari's proposal to secure increased chemical action by glazing photographic studios with violet glass, we pointed out the fallacy upon which we conceived his proposal was based, showing that white glass transmitted all the solar rays, violet as well as others, and that violet glass effected no more. M. Scottelari, referring to our remarks, writes to the *Moniteur de la Photographie* as follows:—

"SIR,—In its impression of the 5th January, the PHOTOGRAPHIC NEWS gives an account of an experiment tending to prove that under violet glass photographic printing goes on more slowly. Although the conditions of the experiment alluded to are altogether different to those upon which I have based my system of lighting studios, I have still every reason to believe that the result would have been, even in this case, favourable to violet light, if only the experiment had been made in a more complete fashion. At the same time, I am glad to see that the very impartial author of the article asks his readers to undertake on their part further experiments on the subject. Here, then, is an experiment which would recommend; it is of an elementary character, and quite within the reach of all. Let a ray of sunlight penetrate a darkened room, the ray coming in through a tiny slit in the shutter. In the passage of this ray interpose a prism. Upon a screen placed at a certain distance will be perceived the beautiful tints of the rainbow, and if the experimenter will now place against the screen a sheet of sensitized paper or any other sensitive surface, he will soon find out the superiority of the violet rays in respect to its chemical action. I am convinced that the honourable experimenter in England, whose results have been given in the PHOTOGRAPHIC NEWS, will make it a pleasure to repeat this experiment, and to communicate his results. Will you agree, &c., SCOTTELARI."

M. Scottelari states here, correctly enough, what is well known to all students and experimentalists in the science of light. That the violet ray is the most chemically active no one will dispute, and a photograph of the solar spectrum will, of course, readily demonstrate this. But if, instead of decomposing the beam of light by means of a prism, M. Scottelari will receive the entirety of it upon a sensitive surface, he will find the whole will produce as much chemical result as did the violet ray when separated by a prism from the other rays.

The case carefully examined is really a very simple one. A window glazed with white glass transmits the whole of the solar rays which reach it, the violet amongst the rest. A window of the same size glazed with violet glass would transmit one-seventh part of the rays reaching it, and these the violet or active rays; but it would not transmit

a single violet ray more than the other window. Hence, unless it be argued that the other rays which are contained in white light are absolutely obstructive, no more actinic power could be transmitted by the second window than by the first. That is the point to be demonstrated in aid of M. Scottelari's position, namely, that the presence of the other elements of white light, besides the violet ray, are not simply inactive chemically, but that they are absolutely obstructive or destructive to the chemical action of the violet ray. Such a theory was, we know, held by some of the old experimentalists, some of whom manifested a tendency to transcendentalism in relation to the new science of light; but general experience has simply proved that the non-actinic rays are inactive, or at least inactive upon the sensitive surfaces which have been hitherto discovered.

And in referring to the chemical activity of light it must always be estimated in relation to the sensitive surfaces which science has so far discovered. Hitherto, with the haloid salts of silver, and the chromic compounds known in photography, the violet ray is active, and the yellow ray without action; but, according to Draper and others, all the rays probably possess photogenic power on some substances. It is possible that M. Scottelari may have evidence to show that the yellow and other rays, except violet, have an antagonistic influence, and obstruct the action of the violet ray on bromo-iodide of silver. And if this be so, it can be demonstrated by direct experiment. Such a demonstration would lead to other important results, and suggest a revolution in the dark room, which, being generally illuminated with yellow light, should tend to obliterate the image which had been impressed by violet light when a plate was exposed for the purpose of development.

When M. Scottelari referred to his experience with a studio lighted through violet glass as giving decidedly better and quicker results, we were constrained to believe that he was under some illusion, induced by a mistaken preconception of theoretical considerations; but courtesy demanded acceptance of his facts. When, however, he refers us, for confirmation of his position, to experiments which we and others have tried many years ago, we feel bound to point out the fact that these experiments do not justify his conclusion that the violet rays of a given amount of white light effect more work than the whole of the white light containing those violet rays.

MORE ABOUT VIOLET GLASS.

MR. GAFFIELD has recently made the experiment of exposing a sensitive bromo-iodized plate under violet glass, and finds the result similar to that on chloride of silver. He says:—

"I made the experiment with Mr. Marshall in his photographic rooms a few days ago, by placing a light shade of violet glass and a colourless glass side by side over a wet, sensitized plate, and then exposing it to light for about a second by pulling out the slide of the shield, and pushing it back again immediately. The result showed, just as I had expected, the fallacy of the claims of M. Scottelari. The plate under the colourless glass was darkened much more sensibly than the portion under the violet, thus proving the inferiority of the latter, which cut off a considerable proportion of the chemical rays.

"From all that I can learn from intelligent photographers and photographic journals, it is a most surprising thing that in France, a country so advanced in scientific knowledge, any company of photographers could be found to give audience to the singular and oft-refuted claims made by M. Scottelari.

"It is undoubtedly true that violet or other coloured screens may be used with advantage in cutting off too much, or in making an even diffusion of light upon the face of the sitter; but it never can be true, while two from six leave a less number than six, that the cutting off of a

third, or any fraction, of the chemical rays of sunlight by violet glass in a screen or skylight can enable the photographer to obtain more rapid or effective results. The use of screens of various colours, and in varying positions, according to the more or less favourable conditions of the weather, or the location of the studio, is almost universal with good photographic artists, and we do not see any novelty in M. Scotellari's idea, or any peg to hang a patent upon."

PHOTOGRAPHY IN THE RUSSIAN ARMY.

THE mobilisation of a large portion of the Russian army on the Pruth has led to some activity upon the part of the staff to perfect as much as possible the science of warfare in the field. For many months past the Russians have been busily engaged in seeking the best information connected with war matériel, and in applying to their own uses such results as have been secured by other nations in one branch of war science and another.

Both in France and in England, it may be remembered, some experiments have been made of late to utilize photography—or, rather, micro-photography—in the topographical departments of the war offices. In France, M. Dagron—whose wonderful pigeon films during the Paris siege must still be fresh in the minds of our readers—has, in conjunction with M. Nachet, an eminent Paris optician, been engaged in reproducing the ordnance maps to a tiny scale, so that hundreds of them could be put into a small space and conveniently carried. Mr. Baden Pritchard, of Woolwich, has been similarly employed on the part of the British War Department, the maps produced by his process being of thin transparent gelatine, toughened by chemical means, and upon a less reduced scale than those of the French government. In the case of Mr. Pritchard's micro maps, roads and routes, as well as names of places, can be made out with a sharp pair of eyes, owing to the remarkable clearness of the details, and are distinctly legible with the aid of an ordinary magnifier, while their weight is such that the whole series of ordnance maps of the United Kingdom could be carried in a pocket-book.

In Russia, steps are being taken to make use of photography in a somewhat similar manner. Colonel Kowako has, it appears, designed a photographic apparatus for the field, which, among other things, serves for the production and enlargement of micro-photographic maps and despatches. The whole affair is in bulk no larger than an ordinary knapsack, and may therefore be carried by a soldier in the field without difficulty. It consists of a perfect photographic laboratory, and contains chemicals sufficient for six months' work.

But the great feature about it seems to be an enlarging apparatus for the amplification of micro-photographs, and which permits of working day and night. Despatches may be enlarged, it is said, 2,300 times, so that there would be no difficulty, supposing the various army corps were each of them supplied with one of these knapsack apparatus, for one general to communicate to another by means of micro-despatches almost invisible to the naked eye.

No precise information as to the details of this compact little apparatus has yet been published, for, as everybody knows, the Russians are peculiarly tenacious in keeping army secrets. We do not suppose, however, that there is much novelty connected with it, and we make mention of the affair simply to show how alive foreign governments are to any improvements which science affords. In this country it has for some time past been the custom to include a photographic equipment in the necessaries of our staff, and in our recent wars considerable use has been made of the art; but the adoption of a miniature apparatus for field purposes is novel, and is, we believe, the first instance of photography being placed in the van of an army. It would be interesting to have some additional information in regard to Colonel Kowako's apparatus, of its capabilities and mode of working; and, no doubt, if war

should unfortunately break out, this will not be wanting. It may be mentioned, by the way, that the first application of photography to warfare took place in Russia during the Crimean war, when two young British officers, having been previously instructed in the art by Mr. Mayall, were attached to our troops in that memorable campaign.

CARBON PRINTING.

BY A. WELLESLEY TURNER.

IN compliance with my promise to render whatever practical aid I could in this process, I will now, discarding for the time all theoretical questions, give your readers as clear and precise an account of the method I adopt as lies in my power. I will imagine for the time that I am at work, so as I can better describe the materials and utensils in use, as well as the method of using them. I have been induced to do this purely from a motive to give carbon printing every opportunity of making itself familiar to the profession, and at the same time I wish to state that I withhold no little dodge or secret in the production of enamelled carbon prints, if any exist, a fact I greatly doubt. The process, I can assure my readers, is a plain and workable thing, if my directions are followed with care and cleanliness. It is a great mistake on the part of those interested in the progress of carbon printing—which we all are, or should be—to keep back any fact connected with its working that would in any way help those who wish to "pick up" the process, as one of your correspondents said was done. I have noticed in the multiplicity of articles on this subject that all the hints and information given on the process have been from time to time published in this journal, but in such a disjointed way that those not acquainted with the process could not necessarily comprehend their value, and consequently taught the uninitiated little more than the fact that the process abounded in endless difficulties, however useful such information may have been to those better acquainted with its details.

Without further comment I will now describe exactly the operations necessary for the production of carte and cabinet enamelled carbon prints, as worked successfully by me, together with my experiences, as far as I think necessary, in each branch. We will commence with the sensitizing, and with this intent I will introduce my readers to the room kept specially for this purpose. It is a comparatively large room, in as cool a part of the premises as possible. In it is an ordinary window with pulleys, opening top and bottom; the panes of glass are muffed with orange paint all over; to obtain a draught of fresh air the window is raised at the bottom, and lowered at the top about six or eight inches, across which is tacked a piece of yellow calico twelve inches wide; this, coming from the inside framework of the window sash, entirely excludes white light, and allows free access of air, which can be closed or not, at will. Immediately under this is a large bench for cutting tissue and transfer paper into the necessary sizes, and also for sensitizing on, on the left of which is a case for keeping the tissue, &c. Across the room is stretched on rings at each side three lengths of strong string with ordinary American clips attached, and this, with the shelves, &c., completes the furniture of the apartment. We will now, with your kind permission, commence operations, the first of which will be the making up of our—

Sensitizer.—This is a very simple compound, and is composed of a solution of bichromate of potash with a small quantity of ammonia. The strength usually recommended is five per cent. bichromate; but I always vary the strength of the sensitizer according to the temperature of the weather, using from four to eight ounces of bichromate to the gallon of water, or from two and a-half to five per cent. In the heat of summer, when the tissue is most sensitive, I use it as low as two and a-half per cent., and gradually increase the strength as the weather gets

colder; and if we have a particularly severe winter I have found it necessary to use a six per cent. bath; but I have not used it over five per cent. this winter; so that it will be seen that this is a matter that requires considerable judgment. But the necessary strength of the bath is easily ascertained by the fact that if the prints produced are much flatter than they should be, and the tissue is more than ordinarily sensitive, then you may know that the bichromate is too strong; and if, on the other hand, the delicate details of the prints wash away during development, leaving ugly white patches, in that case the bath must be made stronger. I prefer my bath to be just past this last condition, as it then gives the most brilliant prints. It is also preferable to have baths of different strengths to suit the class of negatives, a rather stronger one being required for hard negatives with little details in the lights, and *vice versa*. But this, from a practical point of view, is hardly possible when a large number of negatives have to be printed from, and I only have resource to this plan in case I have a great many to print from one negative, and then, of course, I can make up a bath specially suitable. For a bath, however, of five per cent., we will take eight ounces of bichromate of potash and dissolve it in a gallon of water (160 ounces). To do this, I put the bichromate in an ordinary jug kept for the purpose, and pour upon it boiling water; stir this up two or three times, and empty it into a gallon bottle half filled with cold water; this will leave behind in the jug a great part of the bichromate undissolved, to which add more boiling water, and repeat the operation till all is in solution; then fill up the gallon bottle and add about a drachm of ammonia, and when perfectly cooled we are ready for—

Sensitizing.—For this purpose I cut up my portrait tissue into sheets 15 inches by 21, which will, when sensitized, divide into eight cabinet, or four cabinet and eight carte pieces. This is the most economical and convenient size to cut the tissue, and by dividing the whole band in the centre with a fine tool saw previously, we have two small bands in fifteen inches in length, which can be very expeditiously cut into the necessary sizes. The transfer paper I treat in the same manner. I sensitize the tissue by immersing it in the bichromate solution placed in a dish 22 by 26, so that it can be used for large prints, if necessary, up to 20 by 24, although my remarks now more particularly apply to small work. The tissue should be previously dusted, to free it from any adhering particles, and, when in the solution, must be drawn two or three times through the bichromate, so that it flows evenly all over. It must be handled as little as possible, more especially in warm weather. About a minute, as a rule, is quite long enough for it to remain in the bath, although the best test for this is to leave it in until the tissue has a slight inclination to curl, when you may be sure that it has absorbed sufficient sensitizer. I then take it by the two corners, and draw it out of the solution, surface downwards, over a glass rod attached at the near end of the dish, to free it from as much surplus solution as possible. The tissue is then thrown over the string, surface outwards, and previously having arranged a clip at each side, I immediately raise the two corners of the tissue nearest me, and lower it over the string, till, by holding one corner with my left hand, I can allow the other to slip over the string, and catch it with the clip ready opened by the right hand; I then have both hands at liberty to catch the other corner. The tissue by this means is very easily hung up, and it is only touched with the warm fingers for a few seconds at the extreme corners. The solution runs evenly off the tissue, and being freely exposed to fresh cool currents of air on both sides will, in the dampest weather, dry before morning if sensitized over night, and in the middle of summer will not get too hard. This I find the most uniform method of drying the tissue, and giving little or no reticulation of the film. I can say that, without using ice or any other method of artificial cooling, I was only troubled

with a sign of this plague for a few days during the hottest part of last summer, although I must confess that we should have entirely eradicated this bugbear from existence before. I have studied the subject much, but I am afraid I can offer no perfect cure for the evil, beyond advising the use of as weak a sensitizer as possible to give good results, with a short immersion in the bath, and keeping and drying the tissue before and after sensitizing in as cool a place as possible. The use of ice is too expensive, but, as a substitute for this, it is a good plan to keep the bottle containing the bath, during the summer months, in a metal box filled up as far as the neck of the bottle with the coldest water obtainable in that time of the year, or allow a current of fresh water to continually run through the box to keep it cool.

We will now lock the door, and leave the tissue to dry, which we shall find done by the next morning. In the mean time, let me give a few words of advice before I close the subject for the present. It will be seen that I keep a room specially for sensitizing, and I would advise all who can to do so; but in many establishments it could not be spared, especially when only beginning on a small scale; in this case care must be taken that the principle of coolness and ventilation be carried out in the most convenient way to suit circumstances. Dry the sensitized tissue without artificial heat, except in cases when the weather is so damp that the paper by the next morning is still a little tacky, as it will be sometimes. It may then be dried safely by holding it a little distance from a stove, or hung up a short time in a very dry room; there will not then be the slightest danger of the gelatine running off the paper, as it will be well set and contain too little water to do so. Care should also be taken that the sensitizing room is free from foul smells, and do not in any case leave the gas burning in the room to hasten the drying, as these conditions are injurious to the good health of carbon tissue as well as man. Those commencing carbon printing should not do so unless they have everything under favourable circumstances, and with due care, you may make shift with dishes or other apparatus; but you must not overlook the principles upon which the operations are based: a failure in the first trial is more discouraging than a half dozen after you know sufficient of the process to appreciate its qualities. I would certainly advise all who wish to keep pace with the times to try their hands at this process, not as a mere plaything, but carefully and energetically, with the full intent to succeed; and for such I am certain that success, as far as the process has reached that point with others, will be their reward. I would lay particular stress on the fact that it is not a thing to be picked up without study and perseverance; and it is a mistake to employ cheap labour in this branch, especially to commence with. If a photographer cannot find time to do it himself at first, do not leave it to some uninterested assistant printer, or such like, perhaps simply because he has more time to spare than any one else on the premises; like all things, if it is worth doing at all, it is worth doing well, and though it may be found tedious at first, ease and quickness of production will come with practice.

(To be continued.)

A COLLODION WELL.

BY NELSON K. CHERILL.

THE following description of a very simple affair may perhaps be of some use to readers of the NEWS. For my own part I was driven to adopt the expedient of burying collodion in a well, by circumstances to which I may for a moment advert. I had a stock of collodion which I wished to iodize, and keep it for two or three months before use. Collodion should be kept, so we are told on the labels, "in a cool place;" and I had not, at the time of iodizing, any cool place at my command; I therefore determined to try the plan of burying the bottles, which I will now describe. I dug a hole in the garden about two feet deep by one

foot square; into the bottom of this hole I lowered an empty kerosene tin, with the top previously removed. Into this tin I placed the collodion bottles, putting a square piece of wood on the top of the tin, to serve as a lid. Then, on the surface of the ground, over the hole, I placed a piece of matting about two feet square, and on this two or three pieces of rough boarding; and over the whole I piled up earth to the height of about one foot. To prevent the rain washing the dirt down into the hole, I threw a packing case lid on the top of the mound, securing it by a couple of sticks, in a standing position.

About six weeks after my well was complete! and stocked, I went to look at the contents, and found the experiment to have been quite a success; the collodion was ripened, and of the rich colour and perfect clearness that indicate the best working order. The day the well was opened it was very hot outside (thermometer stood about 80° in the shade), but the well was quite cool, as might have been expected. As this plan is so simple, and yet so satisfactory in its results, I intend to adopt it regularly for the future.

I am aware that photographers who enjoy the luxury of having extensive cellars attached to their premises do not require any such expedient as I have mentioned to enable them to keep their collodion in good order; but, on the other hand, there are very many who have not this convenience, or, indeed, any for keeping their collodion as it should be kept; and I fancy that, especially in hot weather, the plan I have adopted will be found very useful. The use of the matting over the hole is to enable the well to be opened without sending a lot of earth into it.

Christchurch, N.Z.

Correspondence.

MEDALS AND EXHIBITIONS.

SIR,—Before the Edinburgh Exhibition took place, I had occasion to speak against the system of awarding medals. I did so chiefly on the ground that five or six men cannot by their award establish the superior excellence of a picture; or, in other words, that there is no exact measure for works of art, and, consequently, that the award of a jury merely shows the opinions of the men who compose it, without establishing the exact excellence of the subjects of their award. It may now be asked, Have the awards made at the Edinburgh Exhibition invalidated my position?

Allow me to state that, along with the other members of the Society, I believe that the jurors, all men of mark, were as good as could be had, and that their opinions are worthy of the greatest consideration. But still the fact remains that these have not been universally received. In the Exhibition rooms I met many photographers, several artists, and a number of other people, some of whom are men of recognised taste in the higher circles of art; but I did not find a single one who thought the prize picture the best in the room. Some preferred other pictures by Mr. Kareline, and some proffered pictures by other photographers.

Mr. Norman Macbeth's very able paper on Mr. Kareline's pictures, in your last number, is well worthy of considerate perusal. Without doubt, Mr. Kareline is an artist, and not merely a mechanical photographer. His pictures are very effective, and carefully finished. But he indulges in peculiarities. He rejoices in strong contrast, one might almost say conflict, of lights and shades; and by introducing white curtains, and large reflecting mirrors, and abounding accessories, he is apt to make these the chief part of his pictures. Even in his prize picture, the chief feature is a long white muslin curtain, against which a man sits in shadow—savouring, it must be said, somewhat of "trick." In his own style, his composition is excellent, and his technic admirable; but, whatever the

reason may be, his pictures generally are deficient in two of the great requirements of art—gradation and simplicity.

It is evident that pictures containing such mingled qualities of excellence and peculiarity give room for very different opinions being formed, according to the point from which they are viewed. On the one hand, we have opinions, worthy of consideration, expressed by the jury; and on the other, we have opinions, equally worthy of consideration, expressed by men of acknowledged taste and culture in art. And to what conclusion does this lead us? Simply to this, that a limited number of opinions on works of art is no criterion of the excellence of said works. This conclusion does not tell against the individuals who compose juries of award. The fault is in the system, which necessitates a jury to give a verdict which they cannot warrant to be correct; and the argument against the system is strengthened by the fact that opinions of our exceptionally good jury do not coincide with the opinions of men who are equally qualified to judge. In short, the motto of the medal system in art is "uncertainty," a by no means satisfactory word.

But we are told that many excellent pictures would not have been sent to the Exhibition if there had been no enticing medals. Let us hope that all the men who sent these many excellent pictures have each gained one of the sixteen silver medals, or at least one of the sixteen bronze medals, or, at any rate, are enabled to enjoy the consciousness that they had good intentions, which no doubt will sufficiently console them in their failure, and encourage them to "put in" for the next exhibition. It is to be feared there are photographers, though they be men of not very high type, whose great desire is to gain a medal, that thereby they may push their trade; whilst others, no doubt, enter themselves for the letters of awards with the feelings which one entertains towards a time-honoured institution. It has been the custom to have medals at exhibitions, and so an exhibition without medals may seem a poor affair. Well! we have had our age of "bronze," and may hope that ere long the love of medals will give place to the love of art, and that photographers will be contented to exhibit their works for the judgment of the public on their own merits, without thinking that the chief end of a photographer is to be distinguished by the sanction of five or six men.

I trust I have said nothing, either in letter or spirit, that seems to bear against the Edinburgh jury, who are all men of high standing. My remarks are directed solely against the system.—I am, &c.,

W. NEILSON.

Edinburgh, Feb. 19th.

PROPOSED MEDAL OF PROGRESS.

DEAR SIR,—Mr. Pritchard, in giving instances of how medals are given abroad for researches in photography cites three instances, in each case foreigners. He might have gone nearer home, as I had the honour of receiving the special medal of the French Photographic Society for the year 1871, an honour I value all the more as coming from another country than my own.

If the suggestion of Captain Abney should ever be carried out by our English Society, I would beg to offer one suggestion: that medals should only be given for published or patented processes. Witness one of the cases cited by Mr. Pritchard, that of M. Rousselon. When, some years ago, I publicly challenged that gentleman to show that the method known as Photo-gravure (Goupil et Cie.), was not substantially the same that I had communicated to him, the only reply was that the process would be published shortly. I have waited in vain through several years for this proof, and have, therefore, every reason to believe that the method adopted by that gentleman is what I have all along believed it to be.

I give this as an instance of how any one working a

secret process—which may be his own, or may not—may become the recipient of an award which he has no right to as original inventor.

WALTER B. WOODBURY.
The Manor House, South Norwood, S.E.

HEAD REST.

DEAR SIR.—Mr. N. K. Cherrill's remarks on head-rests in your issue of the 9th inst. have just come under my notice; and, fully endorsing those remarks, I wish to point out what appears to me to be a readier mode of attaining the desired end, and one quite easily applied by any photographer to any rest he may possess.

Let him procure a half-round or Rattail file of suitable size, and file a channel down the socket in which the rod

slides, thus as at A, and the necessary effect is at once produced. To leave the raised projections as in Mr. Cherrill's sketch would be a work only possible to a skilled mechanic, and then by no means easy of performance.—Yours obediently,

F. LANE.
Rotherham, February 17th.

DALLASTYPE.

DEAR SIR,—I have just seen the paragraph in your last issue, taken from the *Paper and Printing Trades' Journal*, announcing that the *Journal für Buchdruckerkunst* attributes to Pretsch the photo-galvano-plastic process known as Dallastype. The fact is, Dallastype is not a photo-galvano-plastic or photo-galvano-graphic process at all. The *Journal für Buchdruckerkunst* ought to hold its peace, as it meanly burked my letter, published here, exploding the Pretsch claims and Herr Leipold's backing thereof. The facts brought forward were not palatable. They had been published here in the country in which Pretsch had every facility given him that thousands of pounds could procure to prove his title to be considered a man of original invention, or a practical photographer and electrotypist, but miserably failed. If Pretsch had been an Englishman or a Frenchman, *Journal für Buchdruckerkunst*—long, lumbering name—would not have been so ready to credit him with other people's work. Aye, and if he who succeeds where others fail is entitled to what credit may be due, even photo-galvanography—credited, as it has been, to Pretsch—was my work, though not my idea. The honour of the idea belongs to the Imperial Printing Office, Vienna, where experiments were made with Fox Talbot's gelatine and bichromate of potash process. Councillor Auer, the former director of that establishment, stated that the experiments were made under his directions. Pretsch stated that he had never heard of Fox Talbot's discovery, but that he had carried out all his experiments at his own private lodgings. Who is to be believed? Certainly not Pretsch, as it came out afterwards that Fox Talbot's process was described in the "*Journal of the Photographic Society*," and that both Pretsch and the Imperial Printing Office, Vienna, took in that journal regularly.

I enclose you a specimen from a Dallastint block, which has appeared in this month's *Geological Magazine*, and has been machined with the type. The original was an albumen photograph. Perhaps I shall find, some day, *Journal für*, &c., claiming this invention also for the renowned Pretsch!—Yours truly, DUNCAN C. DALLAS.

[The example enclosed is very good for a process of the kind.—ED.]

EMPLOYERS AND OPERATORS.

DEAR SIR,—In your impression of Feb. 16th you have reprinted a paragraph from the *Oxford Times*. I make no comments here upon the spirit in which that report was published, nor need I make any statements to you in reference to my intentions respecting it; but as I conceive that it has been sent to you in a spirit of malice, and with the intention of doing me injury with the public, I must ask you, as a matter of common fairness, to make a statement or two which has been withheld, and which may have the effect of more equally dividing the blame.

Sir, in the first place I admit (and did admit at the court) my legal indebtedness, but I lost so many things through my last two operators, the last six months for which I could not get any redress, as they ran away; and missed goods while Peasland was here, and could not get a satisfactory answer from him. From loss of another kind, arising out of his total inability to do the work for which I engaged him, I did not expect to save myself. This charge was abundantly admitted by him engaging himself to come to work for half the price, an agreement which he never kept. That he was on the whole not badly treated by me will be pretty clear, that he wished me to enter an agreement for twelve months; but as I had frequently to remonstrate with him respecting his general low behaviour, details of which I need not now give, I refused to accede to it. So much, sir, I conceive to be due to myself, in explanation to the one-sided report which you have printed; and I also think to be due to other photographers, who should be put upon their guard against the Peaslands of the profession.—I am, sir, yours faithfully,

J. GUGGENHEIM.

56, High Street, Oxford, Feb. 19th.

[Our correspondent will doubtless see that we could have no feeling in the matter, as we reproduced the paragraph in its entirety from a respectable local paper; another local paper giving substantially similar details. If any injustice is done to our correspondent, or any annoyance caused him, we regret having given the statement currency.—ED.]

Proceedings of Societies.

PHOTOGRAPHIC SECTION OF THE AMERICAN INSTITUTE.

THE usual monthly meeting was held on December 5th, 1876.

The SECRETARY read a note from the President, Mr. H. J. Newton, stating that he could not be present at the meeting.

On motion of the Secretary, Mr. J. B. Gardner was called to the chair.

The minutes of the last meeting were read and approved.

The SECRETARY said that at the October meeting of the Section our President, Mr. Newton, exhibited some silvered paper which had been prepared some eighteen months before, and at the time of exhibition was, to all appearances, in good condition. It may also be remembered that some six years ago he (the Secretary) made some experiments with silver paper, and that on two occasions since that time he had practically tested it, and exhibited the results. To-day it occurred to him to again look at his silvered paper, and, by the date marked on it, he found it was prepared on the third day of the third month, six years and over, and the paper appears yet white and in good condition.

Dr. MILLER said the paper which Mr. Newton gave him he had attempted to use without fuming, and found it gave a very weak print indeed; but he remembered that the President's advice was to place at the back of it a pad that had been immersed in a solution of carbonate of ammonia. This he had done, and the paper printed well. He thought it was rather difficult to tone, but still he regarded it as an acquisition.

The CHAIRMAN said that Mr. Newton's process was to silver the paper, and, when nearly dry, to float it, back down, on a solution of one ounce of hydrochloric acid to forty ounces of water. Now the Secretary's method was to float the paper the albumen side down. In regard to Mr. Newton's mode of preparing paper, he would say that he made some experiments in that line, and found that when the paper was floated on the

back, it required careful handling to prevent it from being wet on the other side. If the paper is in the least way damp, the solution will creep over the edges; and hence he inferred that that method would not come into general use for gallery work, but for amateurs and experimentalists, where time could be given, it may possess advantages.

The SECRETARY remarked that his theory was, that by converting all the silver into a chloride, and then rendering it acid, we could thus prevent the paper from changing. But to do this we must change all the free nitrate of silver into a chloride.

Mr. ANTHONY stated that the main point was to get rid of the free nitrate, and to do this a salt of silver must be formed that does not act on the sizing of the paper, and changes the colour even in the dark. He made paper in which the free nitrate was reduced to a minimum degree, and it has kept well at a moderate temperature; but in hot, damp weather becomes partially discoloured. It is absolutely necessary to have no nitrate in it. By the word nitrate he meant the free nitrate of silver.

Mr. DUCHONNEAU remarked that he washed his paper in water, and then dipped it in a solution of bicarbonate of soda, and it keeps from two to three months; but it does not print as well as freshly silvered paper.

Mr. ANTHONY said that some months ago, eighteen or more, a committee was appointed to experiment in regard to the means of removing the hypo from silver prints after they were fixed, by the use of lead and other solutions, as recommended by Mr. Newton and Mr. Anthony. At the time these experiments were made, there appeared, from the chemical tests used, to be no hypo left in the prints. He would suggest that at an early day, say the next meeting, this committee report to us their present condition.

The CHAIRMAN remarked that if it was the wish of the Section, some of the committee would report and exhibit the prints then made at the next meeting.

On motion of Dr. MILLER, the committee was requested to report at the next meeting.

The SECRETARY said that it would doubtless be gratifying to the members to hear that our President, Mr. Newton, had received the silver medal of the Institute for his prints from emulsion plates, exhibited at the late fair of the Institute.

A lantern exhibition of some exceedingly fine views, taken by Mr. T. C. Roche at Washington during last summer, was next given. The collodion used was made with Anthony and Co.'s new cotton. The views elicited much commendation from the members. After which—

The SECRETARY remarked that he knew that the members felt deeply grateful to Mr. Anthony, not only for this fine exhibition, but for his many other favours to the Section; but he thought the occasion should not pass without some expression on their part that would be recorded on the minutes. Mr. Anthony not only shows us what he can do, but is always willing and anxious that others should present their work also. He would, therefore, suggest to the members to bring to the next meeting, not only their best work, but also their failures, as from them even we can learn something.

Adjourned to the first Tuesday in January, 1877.

MANCHESTER PHOTOGRAPHIC SOCIETY.

AN ordinary monthly meeting of this Society was held at the Memorial Hall, on Thursday evening, the 8th inst., Mr. ALFRED BROTHERS, F.R.A.S., President, in the chair. The minutes of the previous meeting were read and confirmed.

The PRESIDENT called attention to the following resolution of the Council, and requested members to supply lantern pictures and other objects of interest on the occasion:—"That the next meeting of the Society be a social one, and that an extra provision be made at the cost of the Society."

Mr. COVENTRY volunteered to work the lantern on the occasion.

Mr. E. E. Wigglesworth and Mr. S. H. Ashley Oakes were elected members of the Society.

Mr. WADE exhibited a print by the Prussian-blue process. At the time the print was produced, four years since, it was cut in two, and one half exposed to the weather for a month. This half was found to be quite equal to the other, no signs of deterioration being visible in either.

Mr. JAMES YOUNG exhibited a gelatine emulsion plate, which had been dried with a piece of non-actinic paper over it, in which there chanced to be a pinhole. This small aperture had acted as

a lens, and projected an image of a Venetian blind on to the plate, sharp enough to show unmistakably how it was produced.

Mr. NOTON showed a ball-and-socket lens mount for camera front, a la Shadbolt. The "ball" (an oblate spheroid) is three seven-eighths diameter, two inches through, screwed (20) inside to take an outside screw, three inches diameter, or other smaller

size by using an adapter. An angle of twenty degrees from the perpendicular, in any direction, can be had when the lens jacket is two and a-half inches diameter. A much greater angle is obtainable with a lens diameter, a two-inch giving an angle of thirty degrees. The whole of the brasswork weighs seventeen ounces four drachms.

Mr. CHILTON brought before the meeting some transparencies by the gelatine emulsion process—"Franklin's" formula—which were much admired.

Mr. FRANKLAND having exhibited a number of carbon prints by Mr. Higginson, of Southport, which excited great interest, and were much admired, said he had much pleasure in bringing these specimens before the meeting. Perhaps no department of photography had received so much attention of late as carbon printing, which many had attempted, and in which many had failed. Mr. Lambert, however, seemed to have imparted new life and spirit into it, and that which before seemed to be commercially a failure promised to become a success. He (Mr. Frankland) said his friend, Mr. Higginson, was one of the first workers under a licence from Mr. Lambert, and the pictures on the table, sent at his request, were specimens of Mr. Higginson's everyday work. They were not only perfect as carbon work, but as art productions also; and the fact that gentlemen from all parts of the country had visited Mr. Higginson in connection with the subject testified that he had done in carbon what had not previously been accomplished. He (Mr. Frankland) had had an opportunity of going through the whole of the various operations, from the sensitising of the tissue to the stripping of the finished picture, and had concluded that the production of small work in carbon was a commercial success. He hoped the Autotype Company would see the wisdom of returning to their old liberal policy of supplying material to the profession without insisting on a license being taken to enable purchasers to use the materials when bought.

A vote of thanks to each of the gentlemen who had contributed to the interest of the meeting concluded the proceedings, and the meeting was then adjourned.

Talk in the Studio.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At the next meeting of this Society, on Thursday next, 8 arch 1st, at the Rooms of the Society of Arts, Adelphi, a paper will be read by Mr. Peter Mawdaley, on "The Collodio-bromide Emulsion—some of its applications."

FRESH ALBUMEN.—Mr. N. K. Cherrill, writing from New Zealand, says:—"I think I made a note on albumenized paper in a former letter. The material I have the pleasure to see here would be the envy of any brother artist in the old country. Albumenized paper prepared with 'honest albumen' used quite fresh is a luxury that is worth the journey to New Zealand to enjoy. I believe an egg farm in connection with an albumenized paper factory would be a paying game in Europe. I hope shortly to find opportunity to institute experiment on the subject of real egg albumen paper, and for that purpose I have a lot of paper coming out from England; in the meantime I will keep a careful note of all experience in this direction to communicate with you. If, by the re-introduction of a better class of albumen paper, photographers could regain

the point which they had attained ten years ago—viz., that prints would last many years as good as when done—carbon work would not be in much request for small work."

THE NEW AMERICAN JOURNAL.—The *St. Louis Practical Photographer*, the second number of which has just reached us, fully maintains its promise in every respect. It is well printed, well illustrated, and full of vigour and interest in its literary pages. Its advent appears to be hailed with satisfaction amongst American photographers, as supplying a recognized want. We wish it continued success.

SPIRIT PHOTOGRAPHS.—At the recent National Conference of Spiritualists the subject of spirit photographs received considerable attention, and various cases of portraits produced under test conditions were described. It was admitted that cases of imposture had occurred, but others—genuine. It was alleged, beyond the possibility of a doubt—served to strengthen the claims of spiritualism generally. Mr. W. H. Harrison, Editor of one of the journals devoted to Spiritualism, as a scientific amateur familiar with photography, said:—"My opinion is that although, in exceptional cases, spirit photography furnishes about the best evidence of the truth of spiritual phenomena, in the majority of cases it does not do so, and it is, generally speaking, surrounded by such conditions that the study of it can only be pursued in private. In other words, recognizable portraits of deceased friends, unknown to the photographer—the production of which cannot be accounted for on any imposture theory—are the exception. Unrecognizable and indistinct pictures are the rule, and as these latter can usually be imitated with ease by numerous methods of producing sham ghosts well known to photographers, the medium is safe to be assumed to be a trickster by the public, and when his pictures are genuine the populace will not give him the benefit of any doubt, he will be unable to obtain an honest bearing in the newspapers, and any court of law will pronounce him an impostor. A good instance of the production of a recognizable spirit picture was the case in which Mr. Livermore, a partner in one of the largest banks in New York, went to Mamiel, the spirit photographer in that city, and obtained an unmistakable likeness of his departed wife, who was unknown to the man through whose mediumship the picture was produced. Mamiel was pronounced as an impostor, and the expenses of the prosecution were shifted upon the backs of the public, as usual in these cases; but the evidence was so strong that this likeness did not come through any trickery of his own, that, in spite of all prejudices, the case was dismissed. In England he would probably have been condemned."

CONTRABAND PHOTOGRAPHS.—Photographs passing from Canada to the United States are subject to duty. The *Boston Christian Register* says:—"Nearly eleven thousand photographs of the graduating classes at Harvard, Yale, Dartmouth, etc., were seized while on their way from Montreal to Cambridge. 'The duties would amount to about \$3000.' It is to be regretted that so many of the colleges should apparently lend their countenances to smuggling. We regret exceedingly that the good name of our art has been thus tarnished. We now see why it is that all of our large colleges employ a foreign photographer instead of native talent."

A DOUBLE SALT OF SILVER.—Referring to some recent talk in this country about a "new" double salt of silver, Mr. H. T. Anthony says, in the *Bulletin*:—"As I have had some experience with a double salt of silver and ammonia, which I made at the time the Wothlytype process was in use, I may be able to supply a formula for a salt which I know could be used either for the negative bath, or for silvering paper, without removing the albumen from the paper. The process of making it is as follows:—A silver solution of no matter what strength is made into ammonia nitrate in the ordinary way. To this nitric acid is added until the solution becomes acid to litmus paper. Upon being evaporated it gives very fine needle-like crystals. One peculiarity of this salt is that it is much more readily soluble in alcohol than the ordinary nitrate. To use it for the negative bath it is necessary to add a little nitric acid; for the paper bath, a little ammonia. When the subject of emulsions was started in this country, I gave Mr. Newton some of the salt to be tried with the bromide of silver; but as he never reported results, I suppose he did not succeed with it in that direction." A formula for a similar ammonia-nitrate of silver was given in one of our early volumes, alcohol being used for its solution.—*Ed. Photo. News.*

To Correspondents.

DETA.—Bichromatized carbon tissue is much more sensitive to light than silver albumenized paper. But the book illustrations to which you refer are by a mechanical printing process. It is not only quite possible, but easy, to produce carbon prints with a matt surface. The glazed surface to which you refer is produced as a matter of choice, to please public taste.

A. WISOW.—As a rule, photographers are most busy in fine weather. In London, during the London season, now just commencing, photographers are busiest. A good printer receives pretty good wages, we believe, and a really skilful man is rarely long out of employment.

J. C. S.—The question of what lenses to get entirely depends upon the purpose for which the photographer chiefly intends them. If for landscape pure and simple, single landscape lenses answer every purpose, and that you possess, and mark B, is excellent. If they are required for portraiture, a portrait combination is desirable. If for architecture, then a combination, giving straight lines, is necessary. A single lens, used for architecture or for copying maps or geometrical drawings, will give barrel-shaped curvatures to straight lines occurring near the margin. We prefer Y: H has, we believe, gone out of business.

PRULOMEL.—Aurine is a yellow dye colour, which, it is quite probable, will not be kept by ordinary chemists and druggists; but as it has two or three uses in photography, it is probable you can obtain it of most photographic chemists. The sulphide of tin you mention has no connection with it. The latter is the destructive substance which, when used in bronze printing, produces yellow spots in prints. We do not know the price of the lectures you mention, but believe it to be six shillings.

A. PHOTO. PAINTER.—The print has all the appearance of having been in contact with cards on which the name, &c., is printed with the bronze which is used in "gold" printing, which, coming in contact with a print, covers it with the yellow spots seen on your card.

R. G.—We will endeavour to obtain the information.

B. L. M.—You will find on page 162 of our YEAR-BOOK recently issued a reference to all the articles in connection with carbon printing which appeared in the PHOTOGRAPHIC NEWS during last year, a reference to which will aid you materially in your experimental efforts.

TRAO.—Photography as practically worked in the present day is an essentially English discovery. Fox Talbot's discovery was the basis of all silver printing, and Archer's collodion process is universally used for the production of negatives. Carbon printing was based on Mangel Ponton's discovery of the sensitiveness of bichromate of potash in connection with an organic substance; and although Messrs. Poitevin actually formulated the carbon process, Swan and Johnson actually made it practicable. France has, however, made brilliant discoveries in connection with the art. Germans have worked well in connection with the art, but have not done much in the way of discovery. The same of our American brethren. The first photographic journal was, if we remember rightly, published in America, but of late years their journals have chiefly been devoted to the interests of stock dealers, by whom they have been published.

S. V. writes to inform any of our readers who may desire detailed statement of the mode of working the Wothlytype process that it may be found in a volume published some years ago, entitled "Kingham's Amateurs' Manual of Photography." As we before announced, all particulars were also published in various articles in our columns.

H. KNIGHT.—Many thanks. The letter in our next. The example of emulsifying is very good.

AN OLD PHOTOGRAPHER.—The space we can devote to answering correspondents would not suffice to describe in detail the process of producing transparencies by the wet process, but we have frequently published full details. See an article in our YEAR-BOOK for 1876, p. 147.

A. VICTIM TO AN OLD FORMULA.—We have frequently informed our readers that secret formulae offered for sale might by diligent search be found in our pages; but there will always be a certain number who prefer to pay in preference to searching and trying.

JOHN LITKEN.—Sprinkle the negative skilfully with some whitening about the consistency of cream.

B. E. A.—Our YEAR-BOOK has been published for more than a month. The London agent of your bookseller is, we fear, very negligent. He could have obtained it at our office ever since the first week in January. If you send direct to our Publishers, it will be forwarded at once.

VALENTINE.—As a rule, the black india-rubber tubing is pure, and will not injure nitrate solution. A brown earthenware jar is also safe for silver, if it has not been used to hold anything injurious before; but earthenware is often porous and absorbent.

General Correspondents in our next.

PHOTOGRAPHY IN AND OUT OF THE STUDIO

The Government Fund for the Promotion of Scientific Research.—The Government Fund of £4,000, for the promotion of scientific research, is to be applied in the following manner—that is, if the recommendations of the Council of the Royal Society are carried out, as will, no doubt, be the case, either in the shape of grants to persons who have done valuable work, or in prizes of considerable value for the solution of problems; again, money is also to be voted to persons desirous of undertaking special investigations, like the British Association and the Royal Society distribute grants; and, finally, it is recommended that some of the funds would be given to mathematicians and calculators employed upon computations and laborious and unremunerative scientific work. This is the sum and substance of what is to be done with the £4,000 which Government has put on one side for what is termed the promotion of scientific research. We have already criticised the subject in this column, and now that the Council of the Royal Society has made up its mind as to the disposal of the funds, we see no reason for changing the view we have always entertained as to endeavouring to promote research by the distribution of money gifts. Candidly speaking, we think the distribution of money in this way will, if anything, have a retarding rather than quickening effect upon scientific workers, and, for this reason, we do not take much interest in the strenuous exertions now being made by the officers of the Chemical Society to accumulate a fund for a similar purpose. Sometime ago, it appears, Dr. Longstaff made a present to the Chemical Society of a thousand pounds, the interest of which was to be paid to deserving chemists engaged in research, and this, by the efforts of some members of the Society, has been increased to upwards of £3,000—a sum which will be still greatly augmented, it is anticipated. Therefore, what with Government aid on the one hand, and private contributions on the other, there is every prospect of large sums of money being amassed for the so-called promotion of scientific research. How much of this money, we wonder, will flow into the proper channels? The poor and needy investigator, to whom, perhaps, a hundred pounds would be a blessing, will never be heard of among the host of more sturdy and pushing applicants; or, if his case is brought forward, the chances are much against his having sufficient influence with the gentlemen with whom the distribution of the money rests. In such a matter as this, we can only judge of what has already been done by the Royal Society and the British Association, and anyone who takes the trouble to go over the list of annual donations and subscriptions paid over by those bodies will find that in nine cases out of ten the money is given to men of science already in the enjoyment of liberal incomes. Sums of fifty and a hundred pounds are voted to gentlemen in affluent circumstances, who, we suppose, spend the money in fitting up a laboratory or in the purchase of apparatus which they cannot make up their mind to buy on their own account. To say such sums promote research is simply absurd, and if their recipient has, in his time, done good work, it has not been owing to any donation he has received. Mr. Perkin would not have been more expeditious in discovering that magnificent aniline colour termed “Perkin’s purple,” we make bold to assert, had he received a hundred pounds during his investigation; and when he had concluded it, the donation of that sum would have had less influence still. If we could suppose a philosopher so destitute as to be incapable of carrying on a research without funds, and could further suppose that his

case would be fairly treated upon the same basis as the case of the fund for the promotion of scientific research. No special fund is required to meet the needs of the fund. And if the fund has the same disadvantages as the many disadvantages to which it is subjected, it sets up at once a crowd of competitors, who are being seen and recognized. The members of the Society intimate that any who wish to apply for money are to make application to the fund, the envelopes being sent to the fund. How will it be possible to sift the applications and flow in, and arrive at the truth. As we have said before, with the gentlemen who have the advantage of the fund will possess the best chance of getting a share. The main portion of the grant will be adjusted in the main, and we shall see some such statement in the papers, and the conclusion of a cattle or fruit show: "A gift of £15 to Mr. Mathematicus, for his solution of the problem relative to squaring the circle." "A gift of £7 to Mr. Hypothenuse, for his work in trigonometrical survey of the moon." Like the great men and bailiffs of great men, our scientific investigators are rewarded with golden guineas, in the same way as they had reared some prize ox, or grown a Brobdignagian cabbage. Do the promoters of these funds think for our moment that scientific men will refuse to investigate unless they get rewards in future, and that the world is in danger of receiving no more inventions like those of the telegraph, the barometer, photography, aniline dyes, gun-cotton, to name half a dozen discoveries at random? Will a paltry fifty or hundred pounds weigh in the least with a man about to declare to the world some grand invention that he has just elaborated? We think not, and, therefore, we hope to be pardoned when we say that the Government Fund for the Promotion of Scientific Research, as well as any private funds of the same character, are very unlikely to produce material good. In the popular opinion, no doubt, such funds are looked upon very favourably. For it is, naturally enough, inferred that the money will fall to needy and deserving investigators, who have spent their whole time and fortune in the interests of the public. Unfortunately, experience has shown that this is far from being the case, and these few exceptional cases will, we fear, be no better off than they were formerly.

Harmless Logwood and Chromate Inks.—Photographers may be interested to know how to produce a durable ink by the aid simply of logwood aided either to chromate of potash or alum. The ordinary chromium and logwood mixture or ink, it appears, though good and cheap, has the defect of depositing black flakes, leaving a colourless stain behind when exposed to air and light. This may be prevented by the addition of a little carbonate of soda. You add to fifteen parts of logwood extract 900 parts of water, and after leaving the liquid some time, decant it. Then heat the solution, add four parts of crystallized carbonate of soda, and, finally, put in, drop by drop, a solution of one part chromate of potash in 100 of water. Chrome-alum is not recommended, as it gives it a depth of colour, and besides involves the use of sulphuric acid, which attacks steel pens. Another ink which may be employed for copying purposes, and in whose composition yellow chromate of potash also enters, is that recommended by Boettger. Thirty grammes of extract of logwood are dissolved in 250 grammes of water, eight grammes of carbonate of soda are added, and thirty grammes of glycerine; lastly, one gramme of yellow chromate of potash and eight grammes of gum-arabic are powdered and dissolved in a little water. This ink is said to be very black, does not mould, nor attack metal pens.

PHOTOGRAPHY FROM A HOLIDAY-MAKER'S POINT OF VIEW.

BY H. BADEN PRITCHARD, F.C.S.*

I MUST ask you to bear in mind that I am writing not as a photographer, but as a holiday-maker, and that the pictures I show to-night are not the results of photography so much as of holiday-making. My purpose is to put before those who can run away from their work for a week or a month into the country, how much they may add to the pleasure of a tour by taking a little camera along with them; but if they do so, let them never fail to remember one maxim: their chief object being relaxation and enjoyment, nothing should ever be permitted to interfere with their personal pleasure and comfort.

I have heard holiday-makers make a good deal of fuss about altering pre-arranged plans. Nothing, in my mind, is more foolish, supposing you are limited by time and money, as to start upon a pleasure journey without some definite idea of what you are going to do; but at the same time if, during your journey, you perceive a method whereby you can improve your tour, then bear in mind that your sole end and aim is pleasure, and do not hesitate one moment about changing your plans, no matter what trouble they cost you to draw up. You have well earned your holiday—let nothing interfere with your enjoyment of it.

So far as I am concerned, I have made most of my journeys on foot, and when it is borne in mind that I have a knapsack to carry, it will be seen that my photographic apparatus must necessarily be a very small one. Of course, when it comes to rough glacier work the guide or bearer will carry most of your baggage, but a pedestrian always finds many rough journeys to be performed where a guide is either unobtainable or undesirable. You want to linger here or there, and go out of your way perhaps to see a view, fill up an hour or two in some pleasant neighbourhood, take a photograph occasionally, and, in fact, be your own master, which is certainly not the case when you are in the hands of a guide, so that there is no alternative, if you want to be thoroughly independent, but to carry your own *impedimenta*. Before I go any further, I ought possibly to explain myself a little better. I wish it to be understood, for instance, that I do not expect you to go into ecstasies about my results. I myself have a very poor opinion of my photographs as photographs. Some of them are simply atrocious; others, again, are only bad. Nevertheless, I am quite satisfied with them. They are to me very bright reminiscences of pleasant journeys I have made. But they will not bear much criticism. That panoramic view of the Dolomites, for example—and I may here remark, by way of parenthesis, that the Warnerke film lends itself wonderfully for panoramas—will be pronounced, I fear, as black as one's hat, and lacking in detail. I admit it; the sun was shining all the time into my camera instead of upon the object. But I could not wait another fifteen or twenty hours till it pleased the sun to turn round. So I did what I could, and that is the result.

Had I written this paper seven or eight years ago, I should have had to enumerate a longer list of photographic requisites than I find now necessary for my work, and should have considered it incumbent on me, moreover, to have said something about the preparation of dry films, for no one for a moment could hope to practise wet-plate photography under the circumstances in which I am generally placed. In my various journeys I have made trial of many different kinds of films. My Norway pictures were taken upon the early Liverpool dry plates, and upon coffee films of my own preparing; such as I should describe as slow and sure. Mr. England's simple and effective collodio-albumen process has given me that Tyrol series, and Colonel Stuart Wortley's uranium plates, the

clear films of which render them specially suited for enlargement, are shown in my Engadine and Yorkshire prints; and, finally, my sketches of the Dolomites were secured last year by the aid of the Warnerke film.

When carrying dry plates, however, even when I limited myself to three or four dozen films upon thin glass, I found it impossible to carry the whole stock and apparatus myself, and some of it always fell to the lot of my companion. It is surprising, indeed, how half a pound more or less tells upon a tired pedestrian on crossing a pass a thousand feet or so above the snow-line, or after a day's tramp across the Yorkshire moors. I am glad, for my part, that my days of journeying with dry-plates are over; in future I shall carry nothing but a little five-inch camera and the Warnerke roller dark-slide. Together they form a most serviceable equipment; they are carried, as you see, in two leather cases slung over the shoulder; their total weight is three and a-half pounds. A tripod, which is, at the same time, a serviceable alpine staff, and a small wide-angle lens of Dallmeyer's, completes the outfit.

But it is not only in respect to weight that the Warnerke film and roller slide have an advantage over dry plates. Anyone who has a practical experience of the plates and the film will acknowledge this. In the first place, in carrying dry plates, your day's allowance, placed ready in the dark slides for use, may either prove too many or too few for your wants. Your provision for the day is four plates, we will say; in the morning you are very chary about exposing them, and the consequence is, that towards evening you are left with one or two unexposed. Or, again, you use all your plates early in the morning, and have nothing wherewith to secure a picture in the after-part of the day. With the roller-slide you may expose in one day two, or twenty plates, just as you please. Again, there is no changing of plates when you get home, and of all the tedious and distressing labours that a fagged-out pedestrian can be called upon to perform, while his comrades are in bed and asleep, that of unpacking and re-packing dry plates, dusting and labelling them, and putting them in or taking them out of the slides is about the worst. It is often, too, difficult to secure a suitable place for the purpose; in Norway, I remember, I was very much put out on this account. I meant to change my plates as usual at night-time, but found I had reckoned without mine host; to my dismay it was as light at midnight as it is in England on a summer's afternoon. With the roller dark slide such difficulties as these fall away altogether.

Although but little practice and experience are necessary in the production of such little pictures as I show this evening, the novice must not imagine that they are to be secured without some care and trouble. Three main points require particular attention:—Firstly, he must know how to compose a picture in his camera, a matters in which he will experience little difficulty, probably, if he can sketch, or has some little knowledge of art matter; in the performance of this operation, he must bear in mind the nature of the lens he is working with, and especially its greater or less intensity to exaggerate the foreground; secondly, he must learn to focus correctly; and lastly, what is most important of all, he must master the difficulties of alkaline development.

It is, indeed, upon the development of his pictures that success or failure mainly rests, and it is due to my especial shortcomings in this respect that my pictures are as bad as they are. There is no short cut for beginners; they must patiently master the subject by practice. In the development of dry plates patience is the greatest essential, and the success that attended Mr. Manners Gordon as a dry-plate worker was, I believe, chiefly due to the circumstance that he sometimes devoted a whole day to develop and work up a couple of plates.

And now some may ask, Of what use is it to go to so

* Read before the Photographic Society of Great Britain.

much expense and trouble when for a few shillings or francs you might have purchased as many pictures as you ever bring home with you? The answer to this is very obvious: the pictures you yourself take are secured from your own particular point of view, and show you the scenes as you yourself, and not other people, have seen them. I could, no doubt, purchase a view of the Gloss-Glockner for eighteenpence, but the chances are I should not recognise the mountain and its glaciers at all, if I did not exactly know the spot whence it was taken. I prefer a hundred times my own little brown-and-white images, each of which carries a distinct reminiscence with it, and has a story of its own. Besides, my negatives will give me enlargements to any size, such as I show to-night, printed in permanent pigments; or I can produce lantern transparencies in carbon, of which I should have been delighted to have exhibited a series this evening if the apparatus for doing so had not been so cumbersome.

When enjoying yourself on a summer's day in some rustic paradise, it is something to know that you can take back with you a reminiscence that will serve to call up the pleasures of your journey once more; to know that you can bring home a cap-full of the bright sunshine with you, stored up in that film you are exposing; to be assured that you have not seen the last of that glittering landscape at your feet, or of that splashing waterfall among the trees, or that quaint, old-fashioned village through which you have just passed.

ON SUBSTITUTES FOR GLASS FOR DRY PLATES.

BY J. H. T. ELLERBECK.*

LIKE many others, I have been searching for a medium or support for collodion films in place of the weighty and fragile glass. The suggestion made at our last meeting I have not been able to try, the requisite materials not being forthcoming. Mr. Warnerke's tissue is, I suppose, one of the best, if not the best, though I did not succeed with it myself. But, as our president observed a month ago, when speaking on this subject, we cannot make it ourselves, or adapt it to our own pet process.

I tried first gelatine, but the development of a collodion film on this is so risky and so uncertain that it was given up, though, thinking of it since, it is probable that if the gelatine was previously made insoluble, this substance might turn out a valuable material for the purpose. Should any feel disposed to try, the easiest way is to prepare the film on glass, and afterwards coat with gelatine, and strip; or gelatine might be coated with emulsion, as suggested by the Rev. Mr. Palmer.

Next I tried paper; but from what I used (double transfer from the carbon process) the film could not be got away—a good thing, perhaps, if the paper itself did not get stained during development. The one I have now to introduce to you is iron, in that form known as ferrotype plate, smooth. In its favour we have lightness, durability, smoothness, and no reflection from a back surface against it, opaqueness and flexibility, both of which are objectionable; but I hope to show how the objections can be overcome, and its advantage utilised. My mode of using these plates is as follows:—Attach the metal to a glass plate, by means of a drop or two of any fluid, to keep it flat and taut; then coat in the usual manner with a washed emulsion. Perhaps it would be better to mention here that in all these experiments I have used Mawdsley's pellicle, but any emulsion or bath process can be employed. However, the plate, being dried and ready for use, can be at once placed in the dark slide and exposed, either above, before, or behind a glass plate, or backed by a piece of wood to keep it flat; for, necessarily, if springs be used direct they will curve

the thin metal. For use in the changing-box, perhaps the best way is to bind it at the back of a thin glass plate with a piece of gummed paper kept shaped and ready for the purpose. There is thus no possibility of sharp edges of glass or metal catching or hindering in any way the passage from box to slide. A slight frame of wood could easily be made of the thickness of glass, which would then be better, and save weight. Of course, if glass is used, a dozen plates would be sufficient on a long journey, as every night the change of the whole could be made without more than fifteen or twenty minutes' loss of time—not more, certainly, than is usually given for the same purpose with ordinary dry plates; while most of the precautions taken may be dispensed with, for there is no chance of breakage, and little light getting in, even if wrapped up in a single piece of non-actinic paper or calico.

On the exposure of these plates I wish to lay most stress. If one is sure of the right exposure being given the development is an almost mechanical operation. Therefore, do not risk a wrong one. Use the actinometer, and the rest is certain. I had one during last summer's trip, and, although carrying three makers' plates, not one was either under or over-exposed when I trusted it.

Next comes the development. Attach the metal again to a flat support, moisten with alcohol, wash, and apply a five-grain solution of pyro. to every five drachms of pyro; add two drops of bromide of potassium (120 grains to the ounce more or less, according as the image has previously appeared, and reflow over). Add one drop of the strongest ammonia, then another drop or two of bromide, and another drop of ammonia. These, after a little application, will give the necessary density. Fix and wash.

When dry, coat with a solution of gelatine, made by softening in water, draining, and dissolving in alcohol. This enables one to get a dry film quickly. Any ordinary solution of gelatine will do as well, but takes longer in drying. One ounce to 3H₂O, and say three drops of glycerine to prevent brittleness. A cut with the knife at one corner and the whole detaches itself at once, and we have a negative with which we can print from either side, or re-attach to glass, if preferred.

The emulsion mentioned above has for this process the objection that you cannot see with absolute certainty what detail or density you obtain, but I do not anticipate any difficulty on this point if the right exposure be given, and the use of the actinometer determines this. Also, other films, whether washed or preserved, may not have this doubt. Indeed, I remember that with Wortley's emulsion, for instance, you can judge of the development as well by reflected as by transmitted light; so that the opaqueness of the support in such a case would not be of the slightest importance. I may also mention that if expense is no object the alba metal plates can be used in place of the ordinary chocolate ferrotype. Thus the development can be watched with ease, but the alba plates are costly.

I do not offer the above as a finished process. It is more a suggestion which I shall be glad if others more competent will adopt and experiment upon, and that in time for summer work. The great weight of glass we have to carry, the risk of breakage, and the dirt of backing, are great drawbacks to a summer's out. My little camera and two double backs with four plates cannot weigh much more than half-a-pound, and would hardly be a hindrance to any, even if climbing the Matterhorn.

Another advantage of negatives thus obtained is the facility given for combination printing and for making panoramic views, two or more gelatine negatives being joined together without the slightest difficulty; or stereos may be cut and transposed without danger. But I am in hopes of finding a better medium for the transfer of the film from the metal, as there is sometimes a possibility of

* Read before the Liverpool Amateur Photographic Association.

the gelatine, if unevenly or too quickly dried, breaking away in parts. This, however, is not an insuperable difficulty, and can be overcome by slow drying and sufficient body. The transfer paper as used by Mr. Woodbury ought to be the best for this purpose. The price, too, is not much higher than the best glass, and the sheets can be used over and over again, care being taken not to bend or crease them. The transparencies shown are done by this method—group of ferns undeveloped, the first I tried; another a fall, torn through haste. The little bridge, the third done, is perfect—perhaps too dense to most minds; but this was done with more NH_3 than I recommend.

Since writing the above I got some of the autotype temporary support (paper), hoping that this would act as a means of transferring the negative from the metal to glass. It will not; but, in the course of experiments, I find that the paper itself forms an excellent basis for the collodion. Stretching the paper while wet on a piece of glass smaller than itself, and turning the edges under when dry, it can be coated in the usual way with the greatest ease; then cut and placed for exposure between two thin glasses as to save weight under glass, and backed by any lighter material. The development is effected as for ordinary plates, and the result can be watched as easily. When dry it can be waxed for use direct, or, if preferred—as in panoramic or stereoscopic views—transferred to glass by means of one coated with bichromated gelatine, the paper negative being “squeegeed” (if there is such a word) on to it after immersion of both in water for a minute. If the gelatinized plate is kept ready prepared this operation may be performed immediately after washing, if satisfactory. This must then be allowed to dry thoroughly, and the paper comes away easily; but the wax on the paper being soluble in ether and the shellac in alcohol, it may sometimes stick to the gelatine too tight. In this case, if the whole be immersed in alcohol for a while, the shellac is softened, and the paper can be carefully peeled off. The negative must then be varnished. I pass some done in this way.

For this method I see no objection. If a non-inverted image is required, you have it on the waxed paper; if this is of no consequence, transfer to glass. I think, also, that this paper may be more strongly recommended for the gelatino-bromide process, though I have not tried it. Water here being only used, the substratums are not affected, and remaining intact will prevent the paper being stained or from sticking to glass.

I have, as I said before, in all the previous experiments, worked only with a washed emulsion, but hardly expect that the washing of ordinary films would have any damaging effect. What will stand development will surely stand the preliminaries. You will notice that the samples shown vary very much—some bad, some good. I have brought failures as well as successes, as there is more to be learnt from the former than the latter. Thus, one of Furness Abbey is torn by taking the paper off before being quite dry.

You will notice in some the brown colour of the ordinary negative; those have not been toned. The torn one just alluded to is toned by chloride of palladium, and the difference you will see is remarkable. There is also the duplicate of this one untransferred to glass, showing the paper stained. This is caused, not by the development, which left the paper perfectly white and clean, but by the toning salt, the paper holding the hypo. so strongly that the usual washing failed to eliminate it; thus the palladium was precipitated in the paper—stains resulting. It does not spoil the good effect of the transferred film, but spoils my bottle of toner. To avoid all evils, I next used the palladium *before fixing*, and with a weaker solution. The result was satisfactory in every respect, the toning solution being quite uninjured, and the print equally good.

I am afraid I have wandered a good deal in my remarks, but this has been written at various times as the ideas cropped up. I ought, perhaps, to have waited until better results had been produced; but I hurried rather that I might obtain the help and suggestions of those who are more able than myself to work out a new process.

THE DUSTING-ON PROCESS.

BY J. CROSTHWAITE.*

THE dusting-on process is one of the many useful and available processes which have, unfortunately, received but little attention at the hands of photographers in general. A process which combines, as it does, facility of production with scope for the introduction of artistic embellishments, either in the finished picture or on the negative for printing purposes, is certainly worthy of attention.

Its artistic value is at once apparent when I state that the effect to be produced in the picture is almost entirely under the control of the operator. Some portions of the picture may, if desired, be left with the smallest trace of colouring matter, and others may be developed to absolute blackness, or perfect opacity.

In making pictures on opal the vignetting may be carried out in any manner desired, and many most artistic effects may be readily produced. A skilled operator may regulate the light and shade, or balance of the picture, in the same manner that an artist does for the purpose of sinking any portion of the figure, or enhancing its value by contrast, with the advantage that, however he may manipulate, he cannot well destroy the likeness.

It is well known that the artistic value of a picture depends, to a large extent, upon the treatment of the background, which must be subordinate, and still tend to give relief to the figure. A badly-managed, monotonous background, devoid of light and shade or gradation, will certainly detract from any merit the picture may otherwise possess. The reply given by Rubens to a person who recommended his son to him as a pupil, by saying he was sufficiently advanced so as to be able to paint his backgrounds, will never be forgotten,—“If he can, my good friend, he stands in no need of my instruction.” So well did the great artist recognise how much painting was dependent upon that feature for its excellence.†

The various ways in which this process may be utilised are very numerous. In the early period of its existence it was principally used for the purpose of producing photo-enamels; but it is now used in various ways—for the production of negatives for printing or reversed for carbon printing by single transfer, for the production of opalotypes, the intensification of negatives, either as a whole or locally, as in the production of skies and atmosphere, or even to the extent of introducing figures in suitable places. But these manipulations require the assistance of an eye capable of judging of the best effect, and that most in keeping with the subject.

The process is based upon the decomposition of organic matter in conjunction with a chrome salt—not by utilising directly the products of the decomposition, but by a resultant action, consequent upon exposure to light. The action is analogous to that upon which carbon printing, photo-lithography, &c., are based, viz., that bichromated organic matter, in its normal condition—that is, unacted on by light—is absorbent of water and soluble, but by being exposed to light becomes non-absorbent and insoluble. Thus, if we take some organic substance of a deliquescent or hygroscopic nature, sensitize it with a chrome salt, and expose it to light, it follows that such exposure will destroy its power of absorbing moisture; but suppose you expose only one half, and keep the other screened, the protected

* Read before the West Riding of Yorkshire Photographic Society.
† Burnet.

portion will retain its absorbent powers. Of this peculiar action the dusting-on process takes advantage.

It will be seen that the exposed surface will be more or less absorbent of moisture inversely as the ratio of its exposure. The parts that have been exposed to strong light through the transparent portions of the cliché will be insoluble; the portions covered by the dense parts will remain in their original condition, while the parts exposed to the intermediate tones will be more or less "tacky," according to the relative density of the cliché in those parts. If a powder in a fine state of division be brushed over a plate thus prepared and exposed, it will adhere to the surface according to the light and shade of the original. Thus a negative will produce a negative, and a transparency a positive.

There are a number of formulae published for the preparation of the sensitive mixture, of which I have tried several, but find I can work best with the one published by Geymet, as follows:—

Water	17 ounces
Glucose	1½ ounce
Honey	8 drachms
Gum-arabic	6 "
Bichromate of ammonia	3½ ounces
Saturated solution	

The proportion of deliquescent substance may be varied with advantage according to the season, a greater portion being required in summer than in winter, when the atmosphere is often loaded with moisture. A very useful suggestion on this matter will be found in an article in the YEAR-BOOK for the current year, by A. Cowan, under the title of "A Drop of Moisture on a Dry Subject," in which the writer recommends the use of a hygrometer for ascertaining the amount of moisture in the atmosphere. The less moisture present the greater the difference between the readings of the two thermometers, and consequently, more of the hygroscopic compound is required. According to Geymet a larger proportion of bichromate of ammonia produces increased density; a diminution induces a greyness all over the picture.

Unless you are prepared to do a quantity of work straight away, it is better to make up the compound without the sensitiser and add the bichromate as required, as the mixture will not keep for any length of time. After mixing, filter very carefully, as any sediment or dirt is fatal to perfection in the picture, every particle of solid matter forming a black spot, which, if it happen to come in the light of your picture, is rather objectionable.

The glass, having been prepared by immersion in nitric acid, washed, and allowed to dry, is coated with the sensitive mixture. It is better not to polish the plate, but simply, if you are satisfied as to its cleanliness, to warm slightly brush off the dust, and coat. Here, it is probable, you will feel called upon to utter a few strong expressions, as the solution will doubtless refuse to run on the plate, and, most likely, unless you are careful, you will succeed in sensitising your cuffs or shirt sleeves; but with care you will be able to coat a plate by directing the erratic course of the solution with the finger. It will sometimes occur, during drying, that the solution will suddenly leave some portion of the plate, in which case a gentle rubbing with the finger will generally suffice to make it flow. After coating the plate, return the surplus solution to a second bottle, so as to keep the original solution free from dust. The plate may be dried with a gentle heat over a Bunsen burner or a spirit lamp—the latter, perhaps, being preferable.

When the film has dried quite hard and glossy, it is ready for printing upon. Warm the negative or transparency which you are going to reproduce, and place the sensitive plate in contact. Expose in a pressure-frame. The frames constructed for printing pictures upon opal are very suitable. The time of exposure varies considerably,

according to the nature of the light and the quality of the negative—from a few seconds in direct sunlight to twenty or thirty minutes in a weak light. A cliché violent in contrast will suffice with a shorter exposure, while with a very soft negative the exposure will need to be longer, as, contrary to ordinary printing, the longer the exposure, within certain limits, the more vigorous the result.

The plate, having been exposed, take it into a room having a yellow light, but as much light as you can get, as it is necessary to watch well the development. In taking the sensitive plate from the frame, the picture will be faintly visible; if you have been printing from a transparency the image will be of a negative character, and *vice versa*.

At this stage the plate will be found slightly "tacky" from the moisture absorbed during the exposure, which must be driven off before commencing to apply the powder. Were the powder applied to the plate when in this condition, the result would be a most unsightly patch of colours which could not be remedied.

Warm the plate again, and when dry—which may be ascertained by touching the margin of the plate with the finger—lay it on a piece of white paper, so that you may watch its progress, and brush over it the powder, which must be perfectly dry, with a tolerably large soft brush. Cover the plate evenly with a few rapid motions of the brush, which, if the exposure has been correctly timed, will develop a faint image of the picture. Continue the development, with a circular movement of the brush until the requisite density has been obtained. If the development appear to stop before it is sufficiently out, brush off the surplus powder, and allow the plate to stand for a minute or two to admit of its taking up a little moisture from the air, and proceed again as before. It is possible that this may have to be done several times before the picture is sufficiently developed. Should the exposure have been too long, the picture will not develop well, and will refuse to take the colour except in the deepest shadows. On the contrary, should the exposure have been too short, the picture will develop all over, and have a grey, flat appearance, like a print from a much over-exposed negative.

It is probable that the first few plates may not be altogether successful; but by a careful noting of defects, the operator will be enabled, with a little patience, to produce good results.

After development, comes the most critical period, and one requiring great care and delicacy of manipulation—viz., the fixing. Several methods have been given, but the method I have found most satisfactory is by flooding the plate with alcohol, and then allowing it to dry spontaneously. Now immerse in a weak solution of alum until the yellowness disappears, and place for a short time in clear water, dry, and then varnish as usual if a negative, but if a positive, to be coloured upon, use matt varnish.

This process is, perhaps, most useful for the purpose of reproducing negatives, as the quality can be varied and improved. A vigorous negative may be produced from a thin one, and a soft, thin negative from one possessing too much contrast. The process is well worthy of a trial, as there are so many ways in which a power of this kind is useful to a photographer; for instance, when a large number of prints are required, and there is only one available negative, this method enables the photographer to reproduce the negative quite equal to the original, and, if necessary, even to improve it.

HOURS OF SUNSHINE IN LONDON.—The Astronomer-Royal having undertaken to register the hours of sunshine in comparison with the number of hours the sun is above the horizon, some interesting results have been obtained. Thus the week before last the sun was above the horizon 69.8 hours, but his light was intercepted, and he only shone on London 8.3 hours: four days not at all; Sunday, 6.8 hours, Friday 2½ hours; and Saturday, half an hour.

MEDALS AND AWARDS OF HONOUR.

It is probably impossible to award honours or distinctions to any series of competitors without producing some disappointment. The Edinburgh Exhibition was confessedly one of the best and most successful photographic exhibitions which have ever been held. Its scheme of awards was very fully debated when first projected, and, even after its first announcement, was modified in deference to certain objections raised. The jury—chosen on a principle to which it would appear impossible to object, so far as securing freedom from bias was concerned—was composed of a number of gentlemen beyond challenge as to culture and fitness. The issue has not, however, given complete satisfaction, as the letters in our columns bear witness. The case unquestionably furnishes a strong argument for those opposed to the medal system altogether. Mr. Neilson, in a very temperate letter in our last, points out that the especially unsatisfactory element in the medal system is, that its issue is *uncertainty*; that the award of a medal merely expresses the opinions of a certain limited number of, it may be well qualified, gentlemen, who may be precisely opposed to the opinions of a number of other equally well qualified gentlemen. This is doubtless true; but this element of *uncertainty* is, unfortunately, a characteristic of all human operations. The system of trial by jury, which is regarded as one of the corner-stones of our constitution, is liable to a similar charge, and it deals not simply with a man's property or honours, but with his life; and "all that a man hath will he give for his life." But it is constantly staked on the opinions of twelve men who are not experts nor of guaranteed culture or judgment. It is true it is their opinion of facts brought before them in evidence, not of the subtleties of art excellence. And this makes considerable difference. But still we think that the element of uncertainty is scarcely a fair argument against the medal system, as uncertainty of that kind is so prevalent in human affairs. Most judicious thinkers regard the decision of a jury of award as that of so many men whose prepossessions and crotchets modify their judgments.

There can be no doubt the medal question is one involving many perplexities. In our own conviction, it is a system which should be, theoretically, good, and productive of good in its operation. Emulation has been generally recognized in the history of mankind as affording a valuable stimulus to effort and excellence; and certain it is that the offer of medals is so far stimulatory that it always secures a better exhibition. But then comes the unquestionable fact that the awards always cause much disappointment and many heartburnings, and often develop "envy, hatred, malice, and all uncharitableness;" and the question legitimately arises as to whether the good or the evil preponderates. There are some eclectics who

believe in the advantages, and think that the evils might be got rid of if a suitable system of appointing the juries of award were adopted. We remember some time ago hearing of a scheme in which the exhibitors themselves were to be invested with voting powers, and the jury selected by vote. Such a mode of electing the jury ought to render open dissatisfaction impossible; but we fear it would not in any degree mitigate disappointment and dissatisfaction; besides, it is open to a serious objection *in limine*. Photographic exhibitions are open to all comers, whether members of the Society or not, and exhibitors are frequently, to the extent of half or more of their number, non-members of the Society. To invest them, then, with voting powers would be practically to vest in them a certain act involving the expenditure of the Society's funds. It would further place in the hands of exhibitors a power of getting rid of some one powerful rival whose work might stand, beyond all doubt or question, far in advance of his compeers, by nominating him as a juror, and so placing him *hors concours*. We fear, however, that the awards of the most perfect jury which could be chosen, selected on principles the most just conceivable, would fail to give universal satisfaction. And we are bound to conclude that if the possibility of producing bitter disappointment, and even, in individual cases, virulent dissatisfaction, be regarded as a serious evil, the only remedy will be to avoid the medal system altogether.

Regarding the question of uncertainty, there is a cumulative method of securing something like certainty. Some of the medallists at Edinburgh have received many medals before, and the cumulative judgment of many juries of award surely secure something like certainty. On those who received their first medals at any exhibition the argument of uncertainty of course rests; but it will serve, in any case, as a strong incentive to further effort, so as to secure an endorsement, as it were, of the first award. In the discussion as to the merits of the gold medal picture of M. Kareline, we have heard none which effectually traverses the decision of the judges. It has not been alleged that some other picture or contributor was manifestly more worthy. It is alleged that M. Kareline's work was daring, startling, bizarre, and altogether unusual in its photographic character; but it is admitted by all that it was essentially artistic—a quality the jury were certainly bound to appreciate. One of the most prevalent sins in photography is the tendency to a commonplace dead level, and an immense sense of relief is found in anything which, being good and picturesque in itself, effectually breaks that dead level.

The renewal or re-establishment of the medal of progress, proposed by Captain Abney at the last meeting of the Photographic Society, seems to afford general satisfaction; but it will, of course, at its award, be the subject of discussions and challenges, as almost all awards have hitherto been. Already two forms of objection have been mentioned in our columns. Mr. Woodbury points out that, in relation to one of the typical cases in which such a medal had been awarded, which was mentioned at the Society—that of M. Rousselon, who received a medal from the French Society for the invention of a system of photo-engraving—an error existed which he hoped would not be repeated in England. No description was given of the method of engraving in question; hence it was impossible to decide whether it was new and really belonged to the medallist or not. Mr. Woodbury proposes, therefore, that no medal be awarded in cases where the process is not either publicly described or patented. A correspondent, whose letter we are compelled to hold over till our next, agrees with Mr. Woodbury as to publication being a condition, but protests against awarding medals to a patentee, who, he alleges, has selected his mode of reward; choosing the pudding, our correspondent argues, he should not be permitted to seek the praise as well. These and other points will doubtless require careful consideration before any award is made, and are worth considering in advance.

PHOTOGRAPHIC EXHIBITION AT AMSTERDAM.

It is the intention of the photographic body in the Dutch capital to organize an international exhibition during the autumn of the present year. The exhibition will open on the 16th September, and close on the last day of October. Photographers from all parts are invited to take part, and the Committee of Organization have requested a co-operation of all the photographic societies of Europe.

The gathering will take place in the *locale* of the Society *Artiet Amicitia*, in Amsterdam. Exhibitors must apply for space before the 15th July. The prints must be framed and forwarded to their destination before the 1st September, carriage paid. The price of exhibits may be communicated to the Secretary, but must not appear on the frames. A Hanging Committee will be empowered to accept or reject pictures.

Medals will be awarded to the most deserving exhibitors as follows—

A gold medal for the most important exhibit in the province of art or science.

A gold, silver, and two bronze medals for the best photographs in fatty inks.

Two silver and four bronze medals for the best carbon prints (chromotype).

Two silver and four bronze medals for best pictures (not enlargements) above double plate size.

Two silver and four bronze medals for best enlargements; originals to be annexed.

Two silver and four bronze medals for the best portraits, irrespective of size. Untouched portraits will have the preference.

Two silver and four bronze medals for the best landscapes, irrespective of size.

Two silver and four bronze medals for the best studies of animals.

Two silver and four bronze medals for the best microphotographs.

Two silver and four bronze medals for the best reproductions of paintings.

Two silver and four bronze medals for the best lenses and apparatus.

Two silver and four bronze medals for the best clichés on glass, and the best transparencies on glass.

Two bronze medals for exhibitors of the most interesting collection of pictures or photographic apparatus, not of their own production.

Letters addressed to the *Amsterdamsche Photographen Vereeniging*, Amsterdam, will have full attention, and correspondents are invited to write either in German, English, or French, or, we suppose, Dutch, although our brethren in Holland are too polite to say so.

So that there may be perfect impartiality in the distribution of awards, the Society desires to have on the jury as many foreigners as possible; and for this reason the Photographic Society of Great Britain and the South London, as well as the provincial societies in this country, have been asked to nominate one of their members to serve upon the jury of awards.

RAPIDITY IN CARBON PRINTING.

THE relative facility with which carbon and silver printing could be carried on has often been subject of discussion. Mr. Higginson, of Southport, it is alleged, can produce a greater number of carbon prints in a day than could be produced by silver printing, and we are assured by excellent authority that this is a fact. The evidence afforded by the following letter will be found confirmatory of the position. Sir Thomas Parkyns writes as follows:—

"DEAR SIR,—Perhaps you would like to know what I have seen to-day in the matter of the working of Lambert's patent.

"Having been told by a very experienced photographer that the carbon process is slow and very uncertain, many proofs probably being spoiled before the right number of

tints could be arrived at, I provided myself with some of my own negatives which the licensee at Salisbury, Mr. Witcomb, had never seen before. This was intended on my part as a challenge, which was instantly accepted. I let him have them the night before, so that he might have the fair opportunity of touching out any little defects from long use—which was only fair, I think.

"The next morning, about ten o'clock, I took a lady to have her portrait taken. Three negatives were produced in a short time, and we then adjourned to the printing department. There I saw my own negatives put into the pressure frames, the tissue put on them, and then exposed. A real boy did all this—I believe he is sixteen; when asked how many tints the two negatives would require, he said one would take two and a-half, and the other three and a-half. This was actually done, and I saw the tints. The operation next to be performed was the developing, which was done in moderately flat dishes made of tin. I am sorry I did not time each process, but it was certainly quick. The heat of the water was gradually increased from about 80° to what you may term *hot* water. The paper tissue soon came off, and the image appeared rapidly after a minute or two of washing. It was then fixed with alum water. The plates were dried artificially but *slowly*; damped again, as well as the transfer paper, which was at once applied, and well aqueegeed, pressed, and so forth; and the whole gradually dried once more. The result was two excellent prints, to which, however, for landscapes, I objected, on account of the brilliancy of the surface, but was informed that this could be remedied by dipping in water.

"The operation commenced by the negatives being put into the printing frames at exactly five minutes to eleven, and the finished prints (all but trimming and mounting) were delivered into my hands at twelve minutes past twelve precisely. I had to walk a mile to this place to show results to friends, have my luncheon, pack one of the pictures on a roller, &c., write a letter as long as this to Mr. George Avery, of Tonbridge, who does my silver printing for me, the whole being ready to be sent down to the chief Post Office, which closes at 2-45, so as to save that mail. I assure you I was astonished at what could be done. I should certainly say that it is the process for any emergency, whether through impatience or necessity. There was no hurry for the portraits taken this morning, so five were sent in time to be posted at six o'clock, mounted and finished. Two other prints of other negatives of my own were nearly done in the course of the afternoon—two views of the Cathedral. The boy had hit the number of tints for each—one, I believe, required seven tints, and the other nine. They were both more dense than those printed in the morning, and I feel convinced that the secret of the successful and unflinching use (almost perhaps) of the system is the knowledge of the density of a negative, and the nature of the light. There was no mistake on this occasion. The prints were all uniform in tone, and the light decidedly bad the whole day.—I am, dear sir, yours very truly,

THOS. PARKYNS."

FRENCH CORRESPONDENCE.

OBTAINING METALLIC SILVER FROM WASTE SOLUTIONS AND RESIDUES—VIRGIN SILVER—PHOTOTYPES AND PHOTO-ENGRAVINGS BY BOUVIN'S METHOD—DR. FAYEL'S MICRO-PHOTOGRAPHS—A SINGLE MICRO-CAMERA.

AN amateur, M. Fleury Flament, of Lille, has forwarded to me a communication relative to the treatment of solutions of nitrate of silver from which it is desired to extract the precious metal. Operations of this kind, my correspondent tells me, have been with him for some time the object of much research, his efforts being principally directed to the suppression of liver of sulphur ordinarily employed, the odour of which is so insupportable. He has succeeded in his object, and has now elaborated a method by means of which he can extract the silver in a state of much greater purity. Nitrate of silver contained in the old worn-out baths, as

also in liquid residues, is first of all reduced to chloride. To do this, the liquids are put into a porcelain dish or basin capable of holding twice the volume; some hydrochloric acid is then added, until no more precipitate is formed. When the latter has had time to fall and deposit, the exhausted liquid is poured away. The precipitate is treated once more with the same acid, but of no great strength (that ordinarily sold will do well enough for the purpose). The chloride of silver is then washed, in plenty of water, until every trace of acid has disappeared, and finally it is pressed between sheets of bibulous paper. One part, by weight, of this chloride, when dry, is then taken, and intimately mixed with two parts of carbonate of soda in a crucible. When, through the action of heat, this mixture is in a state of fusion, there is thrown into the bubbling mass a few bits of charcoal. Ten minutes afterwards the crucible is withdrawn from the fire, and after cooling, there is found, at the bottom of the crucible, an ingot of silver of a chemically pure character. Although M. Flament inhabits a large town, there is not such means of procuring virgin silver as in Paris, and to obtain this, he treats in the fashion we have described nitrate of silver furnished by dissolving silver coins. In this way he produces a pure silver free from any oxide of copper, which is a constituent of all minted money. It is true that these oxides do not dissolve in the water remaining upon the silver, but they have the inconvenience, when in the mass, of preventing any exact weighing being made.

M. Boivin, who is perseveringly pursuing his labours and interesting researches, has written me a description of a very facile process to obtain engraved plates capable of being printed in an ordinary printing or engraving press. Unfortunately it is impossible, so far, to reproduce halftones by these means; but, nevertheless, the process will be valuable for reproducing linear designs and sketches. When it is desired to produce a block or printing plate in relief, a sheet of zinc or copper is taken some three or five millimetres in thickness. After having grained the surface, it is coated, in a warm condition, with a light film of wax. To this film you transfer a carbon print by ordinary means, and having developed it, it is dipped into alum solution, and dried. Then the plate is plunged into some solvent of wax—benzole, for instance—and in this way those portions of the metal surface not covered by the image are laid bare, ready to be etched with acid; the layers of wax and carbon in the other parts are sufficient protection against any mordant that may be used. It need scarcely be said that when blocks for the printing press are desired, a negative cliché must be made use of; while in that produced of a plate to be printed in an engraving press, a positive image must be employed. Nevertheless, an ordinary negative may also be employed in the latter case; only, if this is done after having produced the carbon picture, the plate must be covered with a film of copper by the electrolytic process. The image may be removed by hypochlorite of lime and boiling water, and then the wax with benzole, and finally acid is employed to etch. In the latter case the copper constitutes the reserve, while the bare zinc plate is etched by the acid. The success of this process of photo-engraving is assured, according to M. Boivin, if use is made of very clear negatives, presenting opaque blacks and whites free from fog. It is indispensable, also, that the pigmented tissue has never been exposed to light previously. M. Boivin finds that the employment of wax is more facile than that of asphalt dissolved in the benzole, recommended by M. Markl for an analogous process.

Dr. Fayel presented to the Academy of Sciences, at the meeting of that body on Monday last, the details of a new method of micro-photography. As I know that the readers of the PHOTOGRAPHIC NEWS are specially interested in such matters, I do not hesitate to bring before them the substance of this communication. Dr. Fayel placed upon a window-sill the microscope he employs for the purpose, which had over the top a small wooden box supported on a tripod.

This wooden box is the camera, which can be fitted and removed at pleasure.* By calculation the author had determined, first of all, and noted upon the exterior, the different heights that the camera should occupy, in order to secure enlargements with the various powers employed, the image refracted by the lens being projected upon the focusing screen of the camera of the same size exactly as it is seen with the eye. Matters thus regulated, M. Fayel takes the microscopical preparation it is desired to enlarge, and reproduces and examines it under the microscope; and when the latter has been properly focussed, the camera is put into its place, without touching either the microscope or the preparation, the eye-piece remaining in its place. He brings the lens down to the point corresponding to the scale referred to above, and, without even taking the trouble to look at the image upon the ground glass, he forthwith proceeds to put a sensitive plate into the apparatus. When the exposure is at an end, the cliché is developed in the ordinary way. The advantages claimed by Dr. Fayel for this mode of operating are the following:—(1), It furnishes to the physiologist the possibility of taking a photographic image of any object visible under the microscope, no matter to what scale it is enlarged; (2), it permits the production of an image without touching the microscope or the object or preparation under it—there is no need even to focus after the camera has been adjusted, because this is done automatically, and always remains the same; (3), it yields an image of the dimensions precisely of that seen through the eye-piece; and, finally, it allows one to transfer to a competent operator all the photographic labours connected with the affair. I may add that the micro-photographs presented to the Academy of Sciences as the fruits of this apparatus were of a most interesting and remarkable character.

ERNEST LACAN.

PRACTICAL NOTES ON VARIOUS SUBJECTS.

BY CHARLES WALDACK.

THE INFLUENCE OF MOISTURE ON THE SENSITIVENESS OF PIGMENT PAPER—THE ADDITION OF AMMONIA TO THE BICHROMATE OF POTASH SOLUTION—THE USE OF ALBUMEN PAPER IN THE CARBON PROCESS—A NEW MODE OF QUICKLY DRYING SENSITIZED TISSUE—A NEW RAPID WET COLLODION PROCESS.

The Influence of Moisture on the Sensitiveness of Pigment Paper.—A fact which must have been generally observed by carbon printers is, that the bichromated pigment paper is considerably more sensitive in damp than in very dry weather. This may be caused by slow drying, which, according to the Autotype Manual, produces greater sensitiveness. It is remarked, however, that paper which has been prepared and left to dry slowly in damp weather will, if dry weather sets in, lose considerable of its sensitiveness, although, according to the notion generally entertained, it ought to become more sensitive by keeping. This would lead me to suppose that sensitiveness does not depend so much on the length of time the paper has taken to dry, as on its degree of dampness. It is certainly very plausible to think that the action of the chromic acid is much more energetic in the presence of a certain amount of moisture, and that as a consequence hard and brittle paper will require a longer exposure than limp and flexible paper. This is borne out by experience, not only in the carbon, but also in collographic printing. Adept in this branch have remarked that their plates are almost devoid of sensitiveness if used immediately on their withdrawal from the drying box, and before they have had time to absorb moisture of the air. It is thus a matter of great importance to the carbon printer, in order to avoid uncertainty in results, always to use the pigment paper of the same degree of dryness; this object can be attained by sprinkling the floor of the room when the paper is apt to dry hard and brittle, and by drying slightly before the fire when it is limp and moist.

* A plano-convex lens was situated inside the camera, which could be moved by the aid of a screw.

The Addition of Ammonia to the Bichromate of Potash Solution.—It has been recommended to add ammonia to the bichromate of potash, in order to produce a certain amount of the ammonia salt, which is supposed to confer valuable properties to the solution. The effect of this addition is to deprive a certain quantity of the bichromate of its excess of chromic acid, and to produce, in this way, chromate of ammonia. Now as the neutral chromates cannot be used for sensitizing, and the bichromates only do so through the free chromic acid they contain, adding ammonia is simply equivalent to weakening the solution, and is a very roundabout way of gaining that object. In practice it must be very difficult, if not impossible, to determine the effects of this addition of ammonia; and unless the opinion entertained is based on comparative experiments very carefully made, which is very doubtful, we cannot be far wrong in looking on it as we do on many suggestions and recommendations in other branches of photography which are not based on well-determined facts.

The Use of Albumen Paper in the Carbon Process.—It would certainly be a great advantage to pigment printing if albumen paper could be used as transfer paper in the place of the very unsatisfactory article supplied. To use it as a single transfer paper it would be necessary to coagulate the albumen. But coagulating dry albumen is a fallacy which has been exploded fifteen years ago in the columns of this journal. Neither boiling water nor dry heat, nor alcohol, have the least effect on the dry albumen, and it is found just as soluble in water after having gone through any one of these operations, as before. Metallic salts produce with dry albumen insoluble substances which, for want of a more suitable name, have been called *albuminates*. Such is the case with nitrate of silver. One carbon printer whom we know used to sensitize his albumen paper on nitrate of silver, and fix it in hyposulphite of soda—a course certainly not to be recommended. A ten per cent. solution of a cadmium salt will produce on the albumen paper an insoluble layer, which has the advantage of being but little affected in colour by sulphurous emanations. Such paper can be used in the single transfer process. In the double transfer process it is necessary to have at the surface of the transfer paper a layer of sticky substance sufficiently thick to fill up the cavities of the image; and the layer of albumen is not thick enough for that purpose, so that the brilliant spots produced by want of contact are invariably produced. The only way to make use of it is the following:—Cover the image on the rigid support while still wet with a ten per cent. solution of gelatine, and let dry. Dip the albumen paper in alcohol, and before this has evaporated, lay it down on the image, which has been previously made wet, and ensure contact by means of the squeegee. A much better way, however, is to save your alcohol, and, instead of albumen paper, use plain photographic paper. The result will be better than if the regular transfer paper has been used. The drawback, however, is that the retouching has to be done after the transfer, instead of before.

A New Mode of Quickly Drying Sensitized Tissue.—One of the Messrs. Geruzet, the enterprising Brussels photographers, who have been using the carbon process exclusively for over two years, has communicated to the Brussels section of the Belgian Photographic Association a new mode of drying the sensitized tissue, the value of which, principally in hot weather, can hardly be over-estimated. The tissue, after sensitizing, is laid on a glass plate and deprived of the excess of solution as usual, by means of the squeegee, after which it is immersed for a few minutes in alcohol, and hung up to dry. The drying is done in about half an hour. The alcohol can be used over and over again, until it has taken up too much water. I am informed that the Messrs. Geruzet also make use of alcohol to dry rapidly the prints on the opal glass after developing, and passing through the alum. This mode of operating was first mentioned by Dr. Van Monckhoven in his *Traité Pratique de Photographie au Charbon*. Messrs.

Geruzet's method, allowing the paper to be sensitized a short time before using, does away with all danger of insolubility, and must prove particularly valuable to carbon printers in North America, where the thermometer during the summer months keeps quite steady among the nineties, and sometimes gets up to 110°. The examples of Messrs. Geruzet, who, as professional photographers, would be interested in keeping a good thing to themselves, deserves to be followed by those of the Lambert licencees who are supposed to reserve a few of the most valuable wrinkles for their exclusive use.

A New Rapid Wet Collodion Process.—It is a fact worthy of note that since the days of Archer no marked progress has been made in the wet collodion process. The two great modifications of the process, iron development and the use of bromides in collodion, although they only became of general use in England ten or twelve years later, were known from the start, and were practised to a certain extent on the Continent, and in a general way in North America. The Winstanley method to reduce the exposure to one-half has fallen into oblivion, and if successful has remained a trade secret with a few. The Monckhoven developer, by the use of which a great reduction of exposure is obtained, has a drawback in the production of a muddy deposit at the end of the development. The same objection is raised against the addition of a small quantity of acetate of iron to the developer. In the opinion of many, progress lay in the use of a bromide and alkaline development. This belief, which I have shared, has been a great deal shaken by the examination of several hundred carte and cabinet pictures, the work of M. Boissonnas, of Geneva. The subject they represent can only have been taken with an exposure so short that you may almost call it instantaneous, and what is remarkable, none seem to be underdone. Babies laughing and crying, with hands and feet lifted up; groups of five and six children, some with cat and dog in their midst; cats in the very act of clawing; groups of dogs and cats; an angry cat with its back up, &c., are some of the specimens of this remarkable collection. These pictures were made with the 28 and 38 Dallmeyer lenses in the studio. I am well aware that under the most favourable condition of light, subjects of this kind can be mastered by the ordinary means we have at our command. Mr. Landy, of Cincinnati, exhibited similar specimens in Vienna and in Philadelphia, which attracted general attention. But with him success is the exception; with M. Boissonnas it is the rule, as is proved by the large number of specimens (about 600) in his albums. On enquiry, M. Boissonnas states that the process he uses is the wet collodion process, with modifications in the collodion, bath, and developer; that he uses it for all kinds of work, and has used it for several years. In an establishment where the mode of working of M. Boissonnas was tested against that in use, it was found that it was seven times as sensitive.

Purple Glass.—In H. de la Blanchère's *Repertoire Encyclopedique de Photographie*, published, I believe, in 1862, I come across the following, page 435, §3:—"On a proposé de construire les vitrines des ateliers photographiques en verres colorés en violet foncé. Sans nier que les qualités de la lumière ainsi transmise sont éminemment photographiques, nous pensons qu'il n'y a pas d'avantage à éliminer tous les rayons des autres couleurs, pour la raison qu'ils ne sont pas tous photogéniques au même degré. C'est refuser bénévolement le concours d'aides un peu moins puissants, mais dont le reunion ne peut être nuisible."

Thus La Blanchère, in other words, expresses the idea that the part is less than the whole. It is remarkable how old fallacies are periodically brought up again. We have had the blue light as early as 1853. It was forgotten, and resuscitated in 1862, when it was used by many photographers in the United States—among others, Fredericks, in New York. A variation of it, the violet

light, seems to have occupied attention in France about the same time. After having been buried and forgotten, it is now brought to light again.

CARBON PRINTING.

BY A. WELLESLEY TURNER.*

PRINTING the sensitized tissue for cartes and cabinets can be done in an ordinary pressure frame, a proper safety edge being provided; but as it is usual now, when doing enamelled carbons, to print in an even tint or ornamental design with name, &c., round the picture, a frame or other contrivance specially made for this purpose is necessary; it greatly enhances the beauty of the finished print, and acts as a guide when mounting with high gloss. Those invented by Mons. Lambert admirably fulfil every purpose; but as I believe they are only supplied to his licensees, and are expensive into the bargain, I would advise beginners, to whom my remarks more particularly apply, to construct or purchase tinting contrivances made on a similar but much cheaper principle. It is simply a method of double printing, the only difficulty to be overcome being the fact that we cannot see the print as in silver, so as to adjust it in position; to do this, however, in carbon is, for small work, an easy matter, all that is required being an arrangement cut out of cardboard in the printing frame, by which the tissue can be accurately placed in the left hand top corner, and marked; when exposed, as usual, under the negative, it is transferred to a similar arrangement in another frame used for tinting, in which the same corner occupies a like relative position to that of the printing frame, the part exposed being covered by the opaque part of the second frame, and over the unexposed part there is only a transparent film, upon which the name or other design is generally printed. It is not, however, absolutely necessary to have the tinted edge for mounting with high gloss, as will be afterwards described under that branch. Where the tinting is not required, safety edges must be provided by cutting masks with the cabinet and carte cutter, and attached to the negatives upon which the tissue is placed, and exposed to light for printing.

As the progress of printing cannot be watched as in silver, we must use the actinometer for this purpose, a little instrument, I think, most of my readers must be acquainted with. The small one, for giving separate tints, if carefully watched, answers the purpose well, and is theoretically the most correct; but as it requires unceasing attention, and considerable skill in getting all the tints alike, I would recommend the graduated ones with numbers (called photometers) for greater convenience. With this instrument, when the number to be printed out is decided on according to the density of the negative, it is only necessary to watch till that number shows itself in the proper depth; practice, of course, is the main thing with this, and with the exposure of the tissue entirely. There is very little I could say to those totally unacquainted with this branch of the operations. The trial of a few pieces of tissue will give the beginner a better idea than if I were to write a volume on the subject. It is a thing that must be wholly acquired by practice, but is so soon learned that any one who has printed in carbon for a short time can regulate the exposure of his tissue with almost as much certainty as his silver brother. If ordinary care is used, I can safely say there is less failure in this branch than any other.

The photometer I have found very liable to become discoloured and stained from constant contact with the silver paper. A good plan to prevent this is to glue a piece of mica inside the photometer over the numbers; this will keep the two papers from coming in contact, and, being very thin, does not hinder the numbers showing distinctly.

Different bands of tissue will also be found to vary in their qualities, some being more sensitive than others, by reason of their absorbing more bichromate, or from other

causes, and requiring a longer or shorter exposure to suit them. All these things require watching, and in it consists the skill of printing; but it is surprising how soon experience makes us acquainted with these features of the case, and how easily methods will be found to obviate them. If the printing is undertaken with the photometer by giving it occasional attention, or setting a boy to watch it under your supervision, you can at the same time be—

Preparing the Plates, which form a temporary support for developing the image on. Patent plate or opal glass is used for this purpose (the latter I prefer, as it enables the operator to better observe the progress of development). The most convenient size is 15 by 12, holding four cabinets or eight cartes. Some like to use a plate for each print, but this, in my opinion, makes the process unnecessarily tedious, although there is some advantage in so doing, as the prints can then, if too dark or not, be separately treated to hotter water or longer immersion if necessary; but I have found that with care there is very little danger in developing the number of prints mentioned on each plate, and, in fact, if this could not be done I should myself feel very much inclined to give the process up as a bad job.

The plates should be kept in a rack conveniently placed over a long bench, with a pad of blotting-paper at one end for polishing the plates on, and the collodion, &c., at the other. It should be as large as possible, as plenty of room is a great comfort in working. Under this bench should be one or two drawers for keeping prints, pads of flannel, &c.

The plates are first laid on the blotting pad, dusted, and coated with wax by pouring upon the centre a small quantity of a saturated solution of yellow beeswax in benzoline, and spread as evenly as possible with a piece of clean old flannel. They are all treated in this manner, and returned to the rack in doing a quantity; by the time the last one is done the first one is ready for polishing. If the plates have not been used before, it is well to wax them a second time, or leave it on some time to thoroughly set, and polish with great care, as with new plates. Unless precaution is taken the prints are very liable to stick when transferring.

The plates are now polished, to remove surplus wax, with a large piece of cotton wool covered with flannel, so as to make a soft pad. Rub the plate well and carefully with this, until a fine even surface is produced, free from all streaks of wax; this is a sure sign the plates are sufficiently polished, and are ready for the collodion. When the plates have been once successfully used, they do not require again cleaning, but are simply polished with a soft chamois to free them from dust, &c., unless the plates become too saturated with wax, and small particles is collodion film get attached to the surface; it is then necessary to clean them with flannel and plain benzoline; that however, is not often required.

I collodionize the plates, when polished, with Mawson's enamel collodion. I prefer this to the ordinary normal kind, as it is less liable to remove the wax, and they will consequently bear more polishing if this is used. When diluted it runs pretty evenly over the plate, although collodion does not in any case flow as well on a waxed surface as upon plain glass, and a little practice is necessary to do this without waste. It is well to have two bottles for this purpose—one for holding the collodion, and another with a large funnel in its mouth to receive that running off the plate. It can be returned to the stock bottle and occasionally filtered and thinned with an equal mixture of methylated alcohol and ether. As each plate is coated it is stood up in a convenient place to thoroughly set, and generally by the time the third one is done the first will be in proper condition for washing, which is done by placing the plates in a vertical zinc dish, with V-shaped grooves, made similar to an ordinary plate-box to hold a dozen or more plates. This is filled with water, and kept at the left hand end of the developing sink (to be next described). They are left in this dish till all the ether is thoroughly

washed out, and the water runs evenly off. It will do no damage to leave them in a much longer time, and, in fact, a quantity of plates may be prepared and left in water till required—although I seldom adopt this plan myself, except when more have been collodionized than necessary for the time. On the other hand, to hasten the washing, it is well to place a flexible tube from the water tap into the top of the dish, and a brass tap being in the bottom, a fresh current of water can be passed through, and by this means the plates will be very expeditiously washed.

The next branch of the operations being a most important one (*viz.* the development), I will reserve my remarks on it, together with a description of the necessary apparatus, till next week.

Correspondence

ENAMELLING PHOTOGRAPHIC PRINTS.

SIR,—As many photographers may not have enamel collodion by them, the ordinary negative collodion will answer quite as well for enamelling photographs, besides which there is a great advantage in that it is always found ready for use, or should be so, in every establishment. The following simple method of procedure will be found useful to photographers in a small way, or amateurs who wish to enamel a few at a time, and will give results equal to any. Take of—

White wax 10 grains
Ether, methylated 1 ounce.

Cut the wax up fine, put it into a bottle, then add the ether, and shake up until dissolved. It will form a milky solution, but does not require filtering.

Take a clean glass plate, pour a few drops on to the surface, and polish with a chamois leather until quite bright; then coat with ordinary negative collodion, and when set and hard, which it would be in about five minutes, put into a dish of clean water for about a quarter-of-an-hour, or wash under a tap until greasiness has disappeared. (The washing effectually removes the iodizing salts and free iodine in the collodion). It must then be stood up to dry, the lower edge resting upon blotting-paper, or dried by heat. Take of—

Gelatine 30 grains
Water 1 ounce

Put the gelatine into the water, and let it remain for about half-an-hour, or until swelled, then dissolve by placing it into a dish of hot water, keeping it stirred with a glass rod or spoon; when dissolved, let it remain in the hot water for about five minutes without disturbing it, when a scum will generally rise, which can be taken off by drawing a strip of paper across the surface. It must then be strained through fine muslin into a glass measure previously warmed. Then take the dried collodionized glass, previously warmed over gas or fire, and pour on the gelatine solution about one and a-half drachms to a $4\frac{1}{2}$ by $3\frac{1}{2}$ plate, and guide it over the surface with a strip of paper or camel-hair brush, and place upon a level surface until the gelatine is set, which will take about ten minutes. Then take the untrimmed print and the gelatinized glass, and put both into a dish of water, carefully examining both surfaces for air-bubbles, which must be removed; and when the print is well saturated with water put it, face down, upon the gelatinized surface of the glass (both under water, and drawn out together), then place upon a table, put a clean piece of blotting-paper upon the top, and press down with the palm of the hand until the excess of water is removed; it can then be stood up in a dry place to dry, which will take about a day, and when dried it can be removed from the glass by cutting round the edges with a penknife.

HENRY KNIGHT.

THE GOLD MEDAL AT EDINBURGH.

SIR,—I am not surprised to see, from last week's News, that it has been thought necessary by one of the judges at the late Edinburgh Photographic Society's Exhibition to come forward and try to vindicate their recent decision on A. Kareline's picture for which they awarded him the

gold medal. It appears to me, however, that instead of returning to the subject afterwards, it would have been much better had these gentlemen expressed themselves more fully in their published report, and explained to everybody at once wherein lay the artistic merit and technical qualities of this wonderful picture over all those other beautiful photographs which covered the walls of the galleries. Had the brusque Dr. Abernethy lived to read this report, he would have been delighted with its brevity, and dubbed the judges the most sensible men he ever knew; while Carlyle's condemnation of verbosity, as expressed in his apothegm that "speech is silvern, but silence is golden," is nearly accomplished in this official paper. Scotchmen are proverbial for caution, and would rather hear the opinions of others before they give their own, and hence, perhaps, the tentative character of the report, with its appendix of "more last words." But be this as it may, the thing is settled; the medal is, no doubt, ere this travelling towards the North Pole, and to prove that it has gone to the right place, Mr. Macbeth sets himself to read a paper on Kareline's method of "lighting the sitter," the perfection of which, he avers, is summed up in No. 775. In the course of his arguments he states that artists and photographers admired this picture, but that "visitors to the exhibition unacquainted with the art were greatly disappointed." It would thus appear that if I or any other photographer should dare to differ from Mr. Macbeth and his friends, we shall be denounced as "muffa," and relegated into the company of those "unacquainted with the art." Be it so. I am quite content that my taste should be measured by this standard, and I cannot do better than allow a visitor to the gallery (a stranger to me) to express his opinion—and mine.

Lady (to her friend, *loq.*)—"Why have they given the gold medal to this picture?"

Gentleman.—"Well, I do not know. It is certainly not a pretty picture, but it is said to have some technical quality, which I cannot understand, that makes it superior to all the others."

Sir, I have great faith in the powers of educated visitors to discriminate when inside a picture gallery, and when they almost all agree to condemn a picture, in spite of the golden spectacles through which the judges compel them to examine it, depend upon it—artists and photographers notwithstanding—their condemnation is likely to be just. In this case I accept the public verdict as my own, in view of the many beautiful and more artistic photographs which we exhibited. But while I do so, I would have it understood that I endorse the praise given to Kareline's work as embodying a new "system of lighting the sitter," which will, no doubt, have its imitators amongst us; and had the judges awarded a medal for that gentleman's magnificent portrait of himself, your correspondent would have felt satisfied. I cannot help saying, however, that with reference to the meeting at which Mr. Macbeth's paper was read, and almost the unanimous echoing of his sentiments by the members present, these modern Athenians fell into the same mistake as those who lived long ago in the ancient metropolis of Attica, and spent too much of their time in "telling and hearing of some new thing." Why should the whole night have been devoted to blowing the trumpet in favour of one exhibitor, with the exception of a single blast, which had better been left in the instrument? Were the works of Robinson, Wane, Nisbett, Kosmata, Dupont, and many others, not worth mentioning in the same breath? Surely, as a matter of courtesy and good taste, this meeting of the Society should not have been closed without a recognition of their merits as well as Kareline's. While giving all due praise to the skill and originality of our Russian brother, we should not forget that "lighting the sitter," be it by inverted light or otherwise, is only a means to an end, not the end itself; unless we are prepared to take the low position assigned us by Mr. Macbeth of being mere copyists. This, I apprehend, photographers will not do, even at the

bidding of an eminent artist, but will rather endorse the sentiments of Mr. Tunny, that a "true artist, whether he is a painter or a photographer, will put his mind into his work, and stamp it with his own individuality." With regard to the awards generally, I will only say that some of those gentlemen who received medals were well worthy of the honour. I dare say Mr. Robinson would be rather surprised, and might possibly think it a mistake, as I did, that a medal should have been given him for "His Own Fireside," while "Preparing Spring Flowers for Market," one of the most beautiful works of art exhibited, was passed over, as being less worthy of the honour. One or two of the lucky men could not fail to be astonished when they woke up in a January morning and found themselves famous, and stamped for the next decade of years as leading men in the profession.

Just one word more, and I am done. Why were the exquisite transparencies of Mr. York ignored? In reproducing the treasures of our nation, which have been accumulating for generations past; in placing within our reach transcripts of those places of deep historical interest which are so much bound up with the past history of our national life, so that tens of thousands of the people who are never likely to visit London and its sights can, in their own homes, feast their eyes and store their minds, by and through his efforts, Mr. York is moving on the lines of and developing what I consider one of the noblest phases of photographic science. I think, therefore, the judges would have done themselves honour in bestowing it upon that gentleman, not only for the beauty and permanency of his work, but for its high educational value in relation to the masses; and for them to have lost the opportunity in this case of giving "honour to whom honour is due" was, to say the least of it, a great mistake.—I am &c.

"ONE OF THE VICTORS TO THE EDINBURGH PHOTOGRAPHIC EXHIBITION."

Proceedings of Societies.

WEST RIDING OF YORKSHIRE PHOTOGRAPHIC SOCIETY.

An ordinary meeting was held on the 5th ult., Mr. JOHN SMITH, President, in the chair.

The minutes of the previous meeting having been read and confirmed, Mr. Shepherd was elected a member.

Mr. J. CROTHWAITE then read a paper on "The Dusting-on Process (see page 100), and exhibited a few specimens of reproductions by that process.

The CHAIRMAN said that he considered the paper a very practical and exhaustive one, and thought the writer had made out a strong case for the process.

Mr. GREAVES inquired if Mr. Crothwaite had tried the process as applied to enlarging.

Mr. CROTHWAITE said he had not, but intended doing so, when he should be happy to communicate the results to the members.

Mr. GREAVES observed that he had tried the formula as given by the Autotype Company in their Manual, but had had great difficulty in getting rid of the yellowness arising from the bichromate. He had tried strong solution of alum and hydrochloric acid for removing it, but had not been entirely successful.

In reply to the Chairman,

Mr. CROTHWAITE said that he had given to the reproductions on the table exposures varying from fifteen to forty minutes. He had found a maximum exposure invariably the best; it simply meant a little longer time in development.

Mr. GREAVES suggested that it would be a very good method of securing vignettes for carbon printing, as the negative might be coated, then printed under an ordinary vignetting board, and developed in any manner the operator thought proper, thus producing a negative that would not require vignetting, but could be printed, like an ordinary negative.

A vote of thanks was then presented to Mr. Crothwaite for his able paper.

Mr. Sachs exhibited a number of pictures printed in carbon, with a surface very highly glazed, as an example of the advantage of slow drying after mounting.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The monthly meeting was held on Thursday, the 22nd ult., the Rev. H. J. PALMER, President, in the chair.

The minutes of the previous meeting were read and confirmed, and Mr. T. Moore was elected a member of the Association.

Notice was given of the intended international exhibition of photographs in September next, organised by the union of Amsterdam photographers.

Mr. J. H. T. ELLERBECK then read a paper "On Substitutes for Glass for Dry Plates" (see page 99). The paper was illustrated by films taken by the methods Mr. Ellerbeck had tried.

The CHAIRMAN also exhibited a negative film which had been produced by gelatine emulsion on a gelatine support. He stated that for small plates gelatine supports seemed to do well, but for large plates he had found a difficulty in preventing cockling.

Mr. ELLERBECK said that using the autotype flexible support that did not occur in working with collodion emulsion, but he intended making further experiments.

A discussion followed as to the most suitable supports for films. Mr. WILSON suggested paper coated with india-rubber dissolved in benzole.

Mr. PHIPPS thought that if albumenized paper was coagulated it would be found available.

The methods of Mr. Woodbury and Mr. Warnerke were discussed, but as the papers used by them were not always to be obtained, it was considered advisable to continue experiments.

A copy of the *Rivista Fotografica Universale*, presented by Cav. A. Montagna, of Mesagne, which was illustrated by an excellent specimen of photo-polychrome, was handed round, and a vote of thanks was passed to M. Montagna. A vote of thanks was also passed to Mr. Ellerbeck for his paper.

The Chairman exhibited an album of photographs containing productions of the London Amateur Photographic Association.

Mr. E. Roberts showed some fine stereo-transparencies obtained by the coffee process, which were greatly admired.

To Correspondents

SUN.—A strong iron developer acts more energetically than a weak one, and permits a shorter exposure. Whenever a short exposure is imperative, it is desirable to use a strong developer—say fifty grains of protosulphate of iron and twenty minims of acetic acid. A strong developer, also, as a rule, tends to the production of soft harmonious negatives, whilst a weak developer tends to produce contrast, hence the strong developer will often correct the excessive contrast produced by under-exposure.

HENRY WILSON.—All intensifiers which pile up the deposit are subject to the defects you name. To begin with, it is, therefore, desirable to use a collodion of a powdery texture rather than one giving a horny film, which readily leaves the plate, and splits, which is somewhat the tendency of that you are using. The application to the film, before it dries, of dilute gun-water or albumen will prevent the splitting and exfoliating.

TRIO.—We will place your letter before the writer of the article. You misapprehend, however, the effect and value of diameter in a lens. It is the angular aperture of the lens which determines time of exposure, and not the diameter of the lens. By the term angular aperture is meant the aperture in relation to the focus.

BLIFFER.—There may be two or three reasons for the film slipping off the plate. The use of a dirty glass will at times tend to this result; the use of a collodion giving a horny film will also tend to the same end; as will, also, the use of an acid bath. One of the best preventives is the use of a preliminary coating of dilute albumen, as we have often recommended in all cases.

LEO.—To retain the full gloss upon enamelled prints, it is desirable to mount them before they leave the plate-glass. Failing that, the only plan to preserve the surface as perfectly as possible is to have a mounting material containing as little water as possible. Glue dissolved in spirit, for instance, answers. India-rubber paste answers also; but it is not a permanent adhesive material. The best mode of securing a good colour in collodion prints is to tone them. A full exposure and rapid development also aid in the production of a warm tone.

W. COLQUHOUN.—The print you enclose—if a photozincograph—is a very good example.

J. L. D.—To intensify or tone with permanganate of potash we have generally immersed the plate in a dish of a ten-grain solution. The colour is a rich deep brown. It has been alleged that it is not permanent; but we have found no failure.

PARFLEXED.—With care it is possible to print from a broken negative without the defect showing much. Place the broken pieces on another plain plate of glass of the same size, and bind them together by placing gummed paper round the edges; then place a piece of tracing paper over the back of the negative. Place the printing frame in a box about the size of the frame, so as to cut off lateral rays, and print only with those which strike the negative perpendicularly.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

THE RELATION OF SITTER AND PHOTOGRAPHER—THE LATEST NOVELTY IN APPLIED SCIENCE.

The Relation of Sitter and Photographer.—Photographers would do well if they placed themselves in the posing chair occasionally, and looked at matters in their studio from the sitter's point of view. As a rule, they are too much given to considering things to their own advantage, and, as we all of us know very well, while papers without number have been written on the subject of governing the sitter, very little has ever been put forward as to the photographer governing himself. The sitter objects to the head-rest; do not heed him, but apply it. He prefers a suggestion as to the manner in which his face should be turned; do not notice it, but proceed in your own way. As a favour, he asks to look at the negative; your strict rule is never to show it. And so on in respect to a dozen other rules which photographers have set up for their guidance. Now there cannot be a doubt as to the necessity of regulations, and strict ones, too, upon the subject of photographic portraiture; but a studio is not a private enquiry office, nor a police court. Neither has it anything to do with a dentist's den, as many a sitter has fancied who has been posed in the "property" chair, more sternly and severely than if a dental surgeon had operated. We do not suppose that very many of our brethren act in this way, but still it cannot be denied for a moment that with the public there is a very widespread opinion that having one's portrait taken has something dreadful about it. This is the point we desire to impress upon the photographer: we wish him from time to time to look upon his method of treating sitters from their point of view alone, and to take the opinion of the outside world upon this or that point in his *modus operandi*. It is perfectly certain, for instance, that to take a satisfactory portrait, under most circumstances, a head-rest is absolutely essential; but it is none the less true that, from one cause or other, many of the public have conceived a violent dislike to that instrument. Gentlemen object to the cold prongs coming in contact with their neck just where the hair fails to give protection; and a lady, when brought face to face with the apparatus, intuitively puts up her hand to the back of her head, well knowing that the ugly claws will sorely disarrange her head-dress. In well-ordered and skilfully arranged studios, it may be said, there is not the least fear to be entertained on either score, and this we are willing to believe; but unfortunately sitters have not yet found it out, and are still chary of trusting their persons in the "torture-chamber." Again, though the photographer may be a most skilful manipulator, and also an accomplished artist, he must remember that, rightly or wrongly, people have their likes and dislikes, and to try to overcome any one's pronounced antipathy is a task not likely to succeed. Ladies, as also gentlemen—for young men are apt to be quite as vain as to their looks as any good-looking coquette—very often conceive the idea that they appear well, or at any rate better, from one point of view than from another, and have a special predilection for the depiction of one side of their face rather than the other. As the result of prolonged studies undertaken before the glass, they have come to the final determination that the right side is fairer than the left, that there is a more palpable dimple to be seen, and—and this is generally the most important of all—it lacks a little black mole which is to be seen on the other cheek, ornamenting it like a beauty-spot. The photographer, on his side, perceives at the very first entrance of his model that her nose inclines just the least bit in the world on one side, as most noses do, and, after another hasty glance, uses every endeavour to get his sitter to sit the reverse way to what she had

intended. He is quite sure she will like the portrait when it is taken, and behold! when the print is mounted and finished, it makes a very pretty little picture indeed. But the photographer's efforts have all been thrown away; the portrait, under any circumstances, would never have been satisfactory, for the young lady has been regretting ever since her visit that she permitted the photographer to change her mind. Sometimes, and not unfrequently, too, it is the dress as much as the sitter—we are talking of young gentlemen now quite as much as young ladies—that it is the customer's ambition to have reproduced, and if, therefore, the photographer only pays attention to the head and bust, he will assuredly fail to please. One disadvantage under which the photographer labours, as compared to portrait painters, is to be found in the circumstance that he never has sufficient time to get acquainted with his sitter. It is rarely the model is permitted half an hour's sitting. In first-rate studios, even, appointments are made which permit the sitter but ten minutes, and when business presses, the model is got rid of more speedily than this. It is hardly possible to do justice when taking portraits in this hurried manner, and, we believe, much of the dislike which some people feel to visit a photographic studio is due to the rapid and rather uncereceremonious way in which they are treated. Nervous persons take some time to settle down and acquire their normal state of mind when introduced into a sphere that is new to them, and the fact that they know very well that as they are that minute, so they will appear in their friends' albums for years to come, does not by any means contribute a soothing effect. The photographer does not consider these little matters enough, and, therefore, we say they would do well to change places with their sitters occasionally.

The Latest Novelty in Applied Science.—The latest novelty in the world of science, though it has no connection with our art, may well find a brief mention in these pages. Electric telegraphy and photography, if they have little else in common, are the two most important inventions of the century, and the latest improvements effected in the former science are well worthy to be here recorded. Some months ago, our readers may remember, an attempt on the part of Dr. Stein to photograph sounds was successful, and speculations were rife as to the possibility some day of depicting speech in the same manner. The telegraph, it appears, has now stolen a march upon its sister invention, and the *Boston Daily Globe* of the 18th ult. records the first successful "talk by telegraph." A message, more than a hundred lines in length, was sent from Salem to Boston, a distance of eighteen miles, and the recipient of the message recognized not only the words, but the voice of the sender. Sounds, as our readers know, differ from one another by the number of vibrations they set up. Thus the sound or note of C answers to 260 vibrations per second upon a string, while to produce D no less than 260 are requisite. So that if as many electric signals are sent through a wire, having a magnet at the end of it, in the proximity of which magnet there is a flexible armature or metal bar, this bar will naturally vibrate a corresponding number of times, and be capable of producing upon a proper instrument any desirable sound. In the case to which we refer, an apparatus is employed called a telephone, the invention of Mr. Gixham Bell. A delicate membrane of gold-beater's skin is stretched near the mouth of the speaker, the membrane having a thin strip of platinum across it, which almost touches another strip of platinum. On talking, certain vibrations are set up which move the membrane, and cause the two platinum strips to make a brisk contact. In this way the vibrations are sent through the wire, and on their arrival at the other end they are made to bring into play a sounding instrument which emits sounds according to the vibrations transmitted.

PHOTOGRAPHY FROM A HOLIDAY-MAKERS POINT OF VIEW.

BY H. BADEN PRITCHARD, F.C.S.*

PEOPLE are apt to make comparisons between scenery at home and that abroad, and that there is a marked difference between the green leafy charms of our own island and the grand views of lake and mountain on the Continent no one will deny. Indeed you have but to glance at those Yorkshire and Cumberland views of mine to mark the contrast between them and those of the Tyrol and Italian lakes. I point this out because there are many who vow that the beauties of Great Britain are altogether unrivalled, and these people, as a rule, never tire of uttering the well worn advice to "see your own country first" before you venture abroad. It is doubtless excellent counsel, but nevertheless, one should be cautious in listening to it, for it comes, maybe, from those who are as ignorant of the pretty nooks and corners in our own kingdom, as of the famous scenes on the Continent they are envious of your visiting. Far be it from me to depreciate the rustic beauties of Great Britain. There are no such woody glens, such fresh green pastures, such stately parks, such white cliffs, such purple moorland, such cool shady lanes as in this sweet country of ours; none in which a plesanter holiday can be spent. But because one has a liking for home-grown strawberries and the dotted cream of Devonshire, it is surely no reason why you should feast on nothing else, and eschew altogether such good things as the black figs of Italy and the luscious peaches of France. And it is as idle, to my thinking, to contrast the flavour of these different fruits as to make comparison between Clovelly village and the Rhone glacier, or the leafy banks of Loch Katrine and the blue Bay of Naples. *Suum cuique*, I would say, and there let the matter rest as regards the scenery of rival countries. But as to the advice of waiting to see your own country before setting foot on the Continent, there are many points to be considered. Some of us have not always the time and opportunity, or that urgent desideratum, a balance at our banker's, and under these circumstances it is wisest, I think, to go when one can. Besides, seeing one's own country may mean much or little, according to whether he who tenders to advise has himself travelled far or near. A traveller may be well acquainted with every great city in the kingdom, and yet have seen nothing of the beauties of Great Britain and Ireland. Short holidays, however, are usually more frequent than long ones, and it is only in the latter case that a trip abroad can be undertaken. One more argument may be advanced against confining your early travels at home: unless you journey abroad when young, you can never appreciate fully the pleasure of foreign travel, for not only are you apt to become prejudiced as years increase, but you desire, more than ever, comforts and luxuries, to be without which means simply to be miserable.

I have said that one charm about photographs taken upon a pleasure journey in this way is, that each of them has its own story. I only wish I could tell you some of them, but my paper has already gone beyond the limits I first intended. I will, however, cite two cases. There is a little picture in one of my Tyrol series; it shows a line of travellers steadily pursuing their journey through a waste of snow. The last is a ghost-like individual, and represents myself, for I had to uncap the lens before taking up my post, and the bright reflection from the snow began to act upon the sensitive film before I could assume my position. That little picture was taken at our resting place, and calls to mind a jolly picnic upon the snow fields just above the Pasterzen glacier that flows round the foot of the Gross Glockner, here, a gigantic sugar-loaf of pure

ice and snow. As we rested we could see the whole broad sweep of this glacier, at first dazzling in its whiteness, and then breaking up, as it descended, into huge crystalline masses of translucent emerald. The glacier encircled the rocks at one's feet like frozen billows, and you felt tempted to descend, as it were, to the beach and toy with the glacial water.

A story connected with two pictures in my English series, and I have done. One of these represents a low stone building, and the other a dirty court-yard with a stable and a pump in the foreground. They are photographs of Dotheboys Hall. I was in Yorkshire, footing it over the moors, through beautiful Wensleydale, ascending Hillbrough, and visiting such out-of-the-way places as High Cup Nick, Cauldron Snout, and Conky Bear; and I may here remark that any one who believes it is necessary to go abroad to get away from town and every-day life should cross from the "High Force Inn," in Teesdale, to Hawes and Ilkwater, and he will find a two days' march before him through a district as primitive and secluded as the greatest hermit would desire. During twenty miles of the way he will scarcely see an habitation, or meet a living soul as he traverses the wastes of moorland and savage defiles by which his way passes. From Teesdale I came down to Greta Bridge, Yorkshire, possessed with an ardent desire to obtain a photograph of Dotheboys Hall. To the village of Bowes is a five-mile walk—Squeers and Nicholas, it will be remembered, drove over in a pony chaise—and then the problem was to find out the spot. The good people of Yorkshire are a frank, open-hearted race, but I somehow had misgivings about the inhabitants of Bowes possessing any love for Dickens, after his exposure of cheap boarding schools, and I proved quite right in my surmise. However, by far the greater portion of the villagers have never so much as heard of Dickens, and a deep-set scheme on my part to have a pipe and glass one evening in one of the ale houses, and so get into conversation with the cronies of the place, was altogether unfruitful. The old landlady of the inn was, however, better informed, and after expatiating on the interesting character of the town, the Roman Encampment, the Norman Castle, the grave of the lovers Edwin and Emma, whose story has been sung by the poet, I cautiously approached "Dotheboys." I at once touched an unpleasant subject, and my kindly hostess waxed so wrath about "young Mr. Dickens," that it was only by introducing the Romans again, and interesting myself in a big five-foot wall in the kitchen, which was supposed to date from that period, and which I tapped and examined with the assiduity of an antiquary, that I found myself in smooth water again. I had found out two things, however: the locality of the building, and the fact that the village people looked with no favourable eyes upon admirers of the great novelist. A search in the dark the same night brought me to my destination, and the next morning I made a further reconnaissance. A long, low, stone building, just outside the village, was the spot, and from the Norman Castle, where I took my camera, a good, if distant, view of the front was obtainable without observation. To take the rear of the building it was necessary to be cautious. I fixed on the place for setting down my camera—on a low stone wall—and estimated roughly how much of the building I could get into my picture. I counted the paces to judge distance, and then focussed an object at a similar interval. My plate was put into the camera, the slide drawn, and, accompanied by a friend, we moved toward the building, and set down the apparatus, turning away from it at the same moment, and becoming much interested in a dog-cart standing in the road. Securing this picture made me bolder. I passed the side-door and looked in. It led into a yard showing the back offices, the well or pump that used to become frozen in winter time, and make it necessary, occasionally, to substitute a "dry polish" for washing on the part of the boys. There, too, was the stable where Smike would rub down the shaggy pony. If I could only get a picture of

* Continued from page 99.

this I should be happy. Some children came out on seeing my companion and myself, and called out, "There's nobody in; there's nobody in." This decided me. I calculated roughly the distance, as before, slipped in a plate, and while my comrade conversed with the children in a moral strain, I placed my camera on a convenient step. Exposure began, and I had just given twenty seconds, when my friend, who had never ceased speaking to the children, whispered in French, "Garde-toi!" I capped at once, and saw behind me a woman approaching up the yard with a big stick. I swept camera, plate, and slide under my arm, and made a clean bolt of it; but the object of the good Yorkshire woman's indignation was not myself, but an unruly cow that had escaped into the road.

MAGNETO-PHOTOGRAPHY.

BY WM. BROOKS.*

FOR many months past I have been experimenting in this peculiar phase of photography, to see if I could corroborate the statements made by Reichenbach in regard to the influence of the magnet on a sensitive photographic plate. I am fully aware that it has been tried by several, and they have given it up. I have spent a great deal of time on these experiments. At first I had nothing but failures, and sometimes only a very faint indication on the plate, although with only gaining this phantom image it gave me encouragement; and now, under certain conditions, I can get an image on the sensitive plate in total darkness in a shut-up box, showing that a sensitive plate is affected when brought within the influence of the poles of a magnet. My experiments I have not yet concluded, and hope at some future time to give a full detailed account (jointly with my friend, Mr. Henry Collen, of Brighton). Our president has this evening asked me to give the results of one or two experiments, as being very peculiar, and at his wish I do so; but at present I cannot invite discussion on the subject, and as I did not intend mentioning to the Society for the present, as I am quite unprepared, not having the plates with me which would show for themselves how far I have succeeded.

I have made my experiments with an ordinary horse-shoe magnet about eight inches long, which I place in a box, poles uppermost, and above the poles a perforated card (about three-eighths of an inch above the poles of the magnet); the card is the size of a quarter-plate, $4\frac{1}{2}$ by $3\frac{1}{2}$, thus—

The letters N S, the cross, and the little triangles are the perforated parts of the card. The part with the letter N is placed over the north pole of the magnet, and S over the south pole. When the card is in position as before stated, the plate is placed one eighth of an inch above the card, making half-an-inch between the poles of the magnet and the sensitive plate. I must not omit to mention that I blackened both the surfaces of the card with Indian ink; not having a brush at hand, I took the solid lump of ink,

wetted it, and rubbed it over the surface of the card, which ground up the surface to a certain extent. Having placed the sensitive plate in its position, I expose in the closed box in total darkness to the influence of the magnet from three to fifteen minutes; the plate is then taken out and developed. Where the perforated parts of the card are sometimes I have developed a negative image, and sometimes a positive image, as if ordinary daylight had had access to the plate; but the strangest part of all remains to be told, and it is this: on exposing one plate, when I developed it, just below the letters N S, and other openings, there was also developed the single line of letters as shown in the diagram of the card, E S I G T, the last being a part of the letter N. I thought this was very extraordinary; no letters were visible on the card; it was an ordinary printed business card that had been used, having all the letters blackened over, and not only blackened over, but ground up by the way I applied the Indian ink; but there were the letters to be seen perfectly sharp on the plate. I looked at the plate and examined the card for a long time, and at last, by looking at an angle across the card, I could faintly (very faintly) see slightly the letters described, but could only see them on the card with great difficulty, but on the plate they were perfectly defined. As the card had been in use for the same purpose some time, I could not remember what card I had used; but after trying what part of a word the letters would form, I found it to be a part of the word designer. I then remembered I had used a business card of a friend of mine. I had several of the same sort by me, and on hunting up a similar card, there was the word on it of the same character of letter. It would have been quite impossible to have photographed those letters on the blackened card with a camera and lens in ordinary daylight, and the fact is that I have not only obtained impressions of the perforated parts without daylight, but I have an impression of an almost invisible image by some means of reflection (for the letters were on the upper surface of the card), and produced without daylight, without contact, and without either camera or lens.

At present I do not offer an opinion on the matter, but only make a statement of the facts as they occurred.

THE COLLODIO-BROMIDE EMULSION: SOME OF ITS APPLICATIONS.

BY P. MAWDSLEY.*

THE first application I will treat of is the adaptability of the emulsion for the preparation of moist plates to be developed in the field. Having recently read a paper on this subject before the Photographic Society of Great Britain, I will now add a few supplementary remarks, with further experience of this method of working.

I see no reason to alter what I said on the occasion referred to, except in a few minor details. For instance: in applying the solution of carbonate of ammonia I think it better to use a small tray or dish, made of any suitable material. I have one of zinc a trifle larger than the plates I work. Into this I put the exposed moist plate, flush it with the ammonia solution, return it to the bottle, and then take on a pneumatic holder and continue development with a solution of pyro in water, restrained, if necessary, with a few drops of a solution of bromide of potassium. When I judge the details are sufficiently out I stop development with a wash of acidulated water. After this, if I choose, I can continue with acid pyro and silver, and when sufficiently dense again flush with the acid water, when the negative may be stored away to be fixed at any convenient time. I have with me a negative still unfixed developed as above.

I will not trouble you with anything further on this subject, but go on to the next application in my paper.

* Read before the South London Photographic Society.

This is the great power it places in our hands for enlarging from small negatives without the usual intermediary transparency. To do this it requires to push development with alkaline pyro until the image is seen to be developed well through. This may be judged of by looking at the back of the transparency, for such it is up to this stage. If it appear sufficiently developed the next step is, instead of fixing with hypo., to dissolve away the image with nitric acid. I use acid and water in equal proportions. The image is dissolved almost immediately, and it has then the appearance of a very delicate negative which will require strengthening, which may be done by exposing it to light, either day or artificial, and the time of exposure is of no moment. Then, having kept the alkaline developer in, flow it over, and allow it to remain on a minute or two, when the result will be a vigorous negative.

I had round an enlarged negative and a transparency, both taken from the same small negative, the only difference in treatment being that one was fixed with hypo. and the other with dilute nitric acid. I have examined both very closely, and cannot detect the slightest deterioration in sharpness from the original negative, which I also had round. The negative has been enlarged about two, and the transparency three, diameters.

From the foregoing it will appear that, when using the bromide emulsion, it is a matter of indifference whether an enlargement be made from a negative or a positive, it being simply a matter for individual convenience. To further illustrate this capability, I had round two 8 by 5 plates, exposed and developed to-day, the one being a negative and the other a positive image.

There is another probable application of the emulsion which at present I do scarcely more than speak of suggestively, and that is the probability of its being used for the production of enlarged paper proofs, which would be valuable in cases where only one or two prints were required. The general defect in developed prints is a heaviness of the shadows, but I believe this defect may be overcome by using a suitable developer; at all events, the only trial I have made seemed to me very promising. There was perfect gradation of tone without the heaviness above mentioned; but, unfortunately, I was called away while the exposure was going on, consequently it was overdone, and gave a flat print. I shall experiment further in this direction, and communicate the results to your Society.

The next application I need scarcely refer to, and that is its suitability for preparation of dry plates. For the production of transparencies for the lantern and stereoscope, Mr. W. Brooks, at the last meeting, read an almost exhaustive paper, and, in fact, appears to have made the subject so completely his own that it is unnecessary for me to say more.

Finally. I may allude to the fact that without the washed collodio-bromide emulsion our esteemed and energetic fellow-member, Mr. L. Warnerke, would have been unable to manufacture the sensitive tissue with which his name is associated, and which for many purposes is of undoubted and great value.

BLUE GLASS IN DISGRACE.

It is not only in relation to photography, as probably many of our readers know, that superior energy is claimed for the light which passes through blue glass over that which is transmitted by white glass: a claim which, in all cases, experience disproves. An article appears in a recent number of the *Scientific American* headed "The Blue Glass Deception." It seems that an American General, General Pleasanton, of Philadelphia, has obtained a patent for utilizing especially the blue rays in curative operations; and the article in question is devoted to an exposition of

the fallacy of the claims made for the blue ray, and showing that light which has passed through violet glass is in no wise different from white light only reduced in power.

General Pleasanton, it seems, states in his specification "that he has discovered 'special and specific efficacy in the use of this combination of the caloric rays of the sun and the electric blue light in stimulating the glands of the body, the nervous system generally, and the secretory organs of man and animals.' He also states that he finds that vegetation is vastly improved by the transmitted blue light.

"These alleged re-discoveries—for the General only claims to have devised the method of utilizing them—were extensively promulgated through the press early in 1871. Subsequently, in 1876, General Pleasanton published a book on the subject, the volume being appropriately bound in blue and printed in blue ink. Recently public attention has again been called to the subject by a New York daily journal. The peculiar kind of glass in question is known as 'pot metal blue,' that is, it is stained a bluish violet throughout, and is not clear glass covered with flashings of blue glass. It is used in greenhouses, &c., in connection with clear glass; and in General Pleasanton's *grapey* it appears that only every eighth row of panes was blue. Some of the results alleged to have been obtained by exposing animals and plants are as follows:—Twenty grape vines, in their second year, after being set out under the blue glass, bore 1,200 lbs. of splendid fruit. A very weak Alderney bull-calf was in four months developed into a strong and vigorous bull. Heifers, when kept under blue glass, may safely bear young when eighteen months old. A weak child, weighing but three and a-half pounds at birth, weighed at the end of four months twenty-two pounds—the light in this instance having come through blue curtains. Two major-generals with rheumatism were cured in three days. A young lady whose hair had come out regained her tresses; and to these must be added various other cures of severe ailments, which we have not space here to recapitulate. The above are the alleged facts; and we propose to consider the supposed discovery in the light of previous investigations.

"With reference to the theories of electricity, &c., advanced by General Pleasanton to account for his phenomena, their absurdity is so complete that we shall waste no time over them. The important question in the matter, and the only one in which the public is interested, is whether or not blue glass is capable of producing all or any of the results imputed to its use. In order to clear the way for the examination of the investigations, the records of which we have carefully collected, let us consider first those which General Pleasanton quotes in support of his views. These are (1) Seenebier's researches, which go to show that the blue and violet rays are the most active in determining the decomposition of carbonic acid in plants; and (2) experiments of Dr. Morichini, repeated by Carpa and Ridolfi, proving that violet rays magnetized a small needle. The first statement has been totally disproved. Dr. Von Bezold, in his recent work on colour, states that 'the chemical processes in plants, as far as they are dependent upon light, are principally caused by the rays of medium and of lower refrangibility. The development of the green colour of the chlorophyll, the decomposition of carbonic acid, as well as the formation of starch, &c., in the grains of the chlorophyll, are induced by the red, green, and orange rays.' The blue, violet, and ultra violet rays, the same authority goes on to explain, influence 'the rapidity of growth, compel the so-called zoospores to move in certain directions, and alter the positions of leaves, &c. In confirmation of this, we have Sachs's experiments in 1872, which show that light, transmitted through the yellow solution of potassium chromate, enables green leaves to decompose over 88 per cent. of carbonic acid; while that passed through blue ammonia copper oxide decomposes less than 8 per cent. This proves the superiority of the yellow ray to

decompose carbonic acid; and this fact Professor J. W. Draper discovered a long time ago by the direct use of the spectrum. In still further confirmation, we may cite the investigations of Voget, Pfeiffer, Selim, and Planchon. The last three have conducted researches in full knowledge of those of General Pleasonton, and their experiments show that yellow rays are more promotive of the evolution of carbon in animals, and its absorption in plants, than any others in the spectrum, the violet rays having least power in these respects, with the exception of the red rays in the case of animals. The absorption of carbonic acid by plants, and its evolution by animals, we hardly need add, are prime essentials to the growth and health of each. The notion that light possesses a magnetizing power on steel was upset by Niepce de St. Victor in 1861. After removing every source of error, he found it impossible to make one sewing needle, solarized for a very long time under the rays of light concentrated by a strong lens, attract another suspended by a hair, whether the light was white or coloured by being made to pass through a violet-coloured glass.

"We can proceed further, and even show that violet light is in some respects hurtful to plants. Caillaud, for example, says, in 1868, that 'light which was passed through a solution of iodine in carbonic disulphide prevents decomposition altogether.' Baudrimont says that 'no coloured light permits vegetables to go through all the phases of their evolutions. Violet-coloured light is positively injurious to plants; they absolutely require white light.' This scientist instituted the most elaborate experiments on the subject, ranging over eleven years, from 1850 to 1861; and the result of all his labour may be summed up in the simple statement that no illumination which human ingenuity can devise is so well adapted for promoting natural processes as the pure white light provided by the Creator. So much by way of general denial of the claims of superior efficacy residing in blue light of any kind.

"Now we have yet to examine the peculiar variety of blue light here used. Sunlight can, by means of the prism, be split into coloured rays, any one of which we may isolate, and so obtain a certain coloured light. Similarly we may obtain light of a desired colour by the use of a coloured glass which will stop out the rays not of the hue required. So that we may obtain violet light from the spectrum or by filtering sunlight through violet glass. When, however, Dr. Von Bezold, as above, asserts that the violet rays have such and such an effect, he means the violet of the spectrum, which has its specific duty to perform in the compound light of which it is a necessary portion. But the violet light of the spectrum and filtered violet sunlight are altogether different things. The first, as our valued contributor Dr. Vander Weyde has very clearly pointed out, is 'a homogeneous colour containing, besides the luminous, the invisible chemical rays without any caloric rays; while the light coloured by passing through violet glass is a mixture of blue rays with the red rays at the other end of the spectrum; and it contains a quantity of the chemical rays belonging to the blue and the caloric rays belonging to the red. In fact, violet glass passes a light identical with sunlight, only much reduced in power, containing but a portion of its caloric, chemical, and luminous agency; being simply deprived of its strongest rays.' And this the spectroscopist has clearly demonstrated. Reduced to its simplest terms, then, the necessary conclusion is that the violet glass acts purely as a shade for decreasing the intensity of the solar light. And in the simple fact that it does so serve as a shade lies the sole virtue (if any there be) of the glass. In 1856, Dr. Daubeny made experiments on the germination of seeds, and in his report is this suggestive sentence: 'In a south aspect, indeed, light which had passed through the ammonia sulphate of copper (blue solution), and even darkness itself, seemed more favourable than the whole of

the spectrum; but this law did not seem to extend to the case of seeds placed in a northern aspect where the total amount of light was less considerable.

"In our next issue, we shall review the effects of light and darkness upon the animal organization, and endeavour to account for the curing of diseases and the production of other phenomena which have been erroneously ascribed to the influence of the blue filtered sunlight."

SCOTELLARI'S METHOD OF LIGHTING WITH VIOLET RAYS.

[Report of the Commission nominated by the French Photographic Society to examine and investigate M. Scotellari's proposal.]

The Commission which you nominated to undertake an experimental investigation of M. Scotellari's method of lighting portrait studios, a method which, in the opinion of the author, should greatly shorten the period of exposure, met, in the first place, at the studio of M. Joliot, whose glass room had been prepared, to the extent of one half, upon M. Scotellari's principle, and illuminated by violet light, the other half remaining in its ordinary state, or, in other words, lighted with white light. Many experiments were made in the presence of the Commission, but none of the results were sufficient to warrant the conclusion that any marked acceleration was effected.

M. Scotellari, having himself made some experiments at M. Carotte's studio, and having stated that his process had the effect of really abridging the exposure considerably, the Commission, in order to convince itself as clearly as possible, paid a visit to M. Carotte's studio, and made some further experiments in that locale. In this case there was indeed a difference to be remarked in the time of exposure in the portion of the studio illuminated by white light and that illuminated by violet rays, to the advantage of the latter. But the conditions of lighting were not identical. That portion of the atelier lighted by white light was opposite a very high and grimy wall, while the half of the studio illuminated by violet light was surrounded with a good deal of clear sky, which fully justified the difference observed in the time of exposure in the two portions of the studio.

As this experiment was not sufficiently conclusive to satisfy the Commission, it assisted at a third trial in M. Liebert's studio. In this case the glass room was admirably disposed for observing the least difference in the two modes of lighting, if it really did exist; but two exposures, conducted with the greatest care and precaution, did not substantiate M. Scotellari's affirmation, for no difference whatever was to be observed between the two results furnished.

In consequence, the Commission regrets to declare that the great desideratum for portrait photographers, an abbreviation of the exposure, is not attained by means of this process.

The Commission consisted of MM. Franck de Villecholle, Liebert, et Ferrier.

ALUM AFTER FIXING.—A printer from Massachusetts gives the *Philadelphia Photographer* a very unfavourable report on the use of alum between toning and fixing to prevent blisters. He practised it for some months about three years ago, and the results have proved most disastrous, the prints having all been attacked in a short time with the worst kind of yellow fever. Some of the prints we have seen are pitiable in the extreme. This printer has made no experiments to prove the alum at fault; but his work, treated the same in every respect except the alum, both before and after using it, shows no signs of fading.

PICTORIAL PHOTOGRAPHY IN AMERICA.

We have often received from the United States very fine examples of technical photography, and of late years we have received many examples of portrait photography lacking in no form of excellence, presenting fine art qualities, as well as very admirable photography. But hitherto we have seen very few examples of pictorial photography produced in America. We have recently been favoured by Mr. Kurtz, of New York, with a very charming picture produced by photography. It is a large picture, and ambitious in its aim, and is to illustrate some verses by a German poet. It is entitled *Maienacht* (May-night). The lines, which are by George Asmus, run as follows:—

In dunkelfeuchter Maienacht,
Leuchtkäferchen nur glüht,
Verstohle noch manch herrsche wacht,
Was blühe kann das blüht.

Und's mädchen untern Flieder,
Da drin es Hantling baut
Drucht sich die hand aus mieder
Und seufzt enaus halblaut
Ach, wer heint es sohats hatt!

The picture presents a comely German girl standing within a porch, on the damp May-night, looking out into the gloom with a look half of speculation, half of expectancy, waiting for a lover to come. The background, consisting of the porch with lilac growing beside it, is in obscurity, as is also part of the girl's figure, the upper part of which and the head are lighted apparently by an unseen lamp, the picture presenting striking and effective light and shade, the latter prevailing; but perfect breadth is maintained, and the lights are sufficiently carried through the picture by various accessories, receiving light from the same source as the head. The rustic figure, with a pleasant face characterized by unsophisticated simplicity, is admirably rendered; but the charm is in the composition as a whole, which is thoroughly pictorial and poetical, and challenges examination as a picture rather than as a photograph. It gives an impression even to experts that it is a copy of a painting rather than a photograph from nature. After a due examination and appreciation of its pictorial merits, we naturally proceed to scrutinize its photographic characteristics, and there we find sufficient to puzzle and perplex us. The photography is exceedingly good; that is a matter of course in the work of Mr. Kurtz. But here are qualities of texture and handling which are not easily explained. Here are the essentially photographic qualities of drawing and texture, which in the face and some

other parts of the figure permit no doubt that they are really photographed from nature; but in the background and accessories generally, and in many parts of the drapery, there is a peculiar texture which belongs to artistic or artificial handling; a peculiar granulation which unquestionably adds to the artistic effect of the picture; but somewhat difficult to account for in photographic work. The negative has undoubtedly been skilfully manipulated; but the grain or texture of which we speak is not of the character which could be obtained by stippling on the negative. It rather resembles the grain we have seen in Mr. Brown's mezzotint vignette, in which the grain is obtained by double printing from a grain negative. This grain prevails in the backgrounds and in some parts of the draperies and shadowed part of the figure. The face and lighter draperies are quite free from any grain, but possess the ordinary texture of photographic gradation, except that some broad lights are stopped out in the white drapery. In the deepest shadows there is some hatching with an etching point to get deep digs of black. Altogether the picture is an exceedingly interesting photographic study as well as a good picture, and an admirable illustration of the plasticity of photography in the hands of an artist.

PHOTOGRAPHY IN LACE FACTORIES.

In South Germany, we are told, the assistance of photography is aptly made use of in lace factories in the production of *dentelles à l'aiguille*, and at a lecture recently delivered at Vienna by Dr. Martin, the former president of the Vienna Photographic Society, that gentleman gave an interesting demonstration of the art in this connection.

It appears that in this particular description of lace there is considerable difficulty experienced in securing the fabric uniform, some of the work-girls making it too fine and others too coarse. It is made in pieces, which are subsequently fitted together, for it would be practically impossible to wait until one hand had made a piece of sufficient size. A large number of girls are therefore employed on separate parts, which go to make up a perfect piece, and which therefore must all of them resemble each other as nearly as possible.

The ordinary method is to supply the work girls with outline sketches or designs upon straw paper, in which the ground, so far as its dimensions are concerned, is but roughly marked with coloured strokes. Under these circumstances it often happens that the work of the girls varies considerably in regard to the size of the holes and the breadth of the margins, so that there is a want of harmony in a parcel of the lace, a circumstance giving rise to the necessity of carefully sorting out pieces to fit one another, so that no awkward joins may be apparent.

To avoid any such difficulties, it is now the custom to pick out the cleverest work-girl and let her commence upon a design given her upon straw paper. She finishes a piece in accordance with this design, and this well-executed piece of work is then stretched in front of a black background and photographed. The cliché obtained, a Lichtdruck block is produced, and from this a large number of copies are struck off. Each work-girl receives a copy of the photograph, so that not only has she in her possession an outlined design, but the equivalent of a piece of finished lace, which she has merely to imitate, in order that a uniform parcel of work may be secured. A very large number of girls may be employed upon one design in this way, without the manufacturer being under the least apprehension that the many results will vary in character. He can therefore conduct his business with less anxiety, and with the certainty of securing uniform work.

In this application photography appears not merely as a multiplying medium in the matter of design, but as fulfilling an integral part in lace manufacture.

TRANSATLANTIC WRINKLES.

BY LAFAYETTE HARRISON.

No. I.

SINCE having arrived in this country, I have become acquainted with many photographers, and have seen their various manners of working. It would be worse than arrogance for me to say that during this intercourse I have gathered no fresh ideas, or that I have seen no department or operation conducted upon better principles than in America; on the contrary, I have both seen and learned much. But so many suggestions that I have incidentally let drop in conversation have been adopted, tried, and approved by English photographic artists, that I have been requested to communicate some of them to the readers of this journal. Much that I shall herein jot down has appeared before in print (if not in this country, at least in American publications), much is already known, but not universally carried into practice. However, the reader will perhaps be pleased to have them brought once again before his notice, and I doubt not that some few at least will be profited.

Don't be too conservative; give the "wrinkles" a trial. It will pay.

While "out West" last summer, I received a letter from a London photographer which amused me, for it detailed a discovery made by an eminent artist, which had been in daily use, in almost every studio in America, for many years. It was an idea for copying or enlarging photographs (silver prints) without showing the grain of the paper. It is quite simple.

Soak the print to be copied in water. Place a clean negative-glass in a printing-frame. Lay the wetted print face downwards on the glass. Insure perfect contact with a squeegee. Behind it place some moistened blotting-paper. Put in the back of the frame, fix it up, and copy *through the glass*, and you have a copy as good as the original—free from granularity—right away.

That which has struck me more than all else has been the remarkable pertinacity with which English photographers (even the best) stick to the old-fashioned method of polishing plates, in lieu of using a substratum of albumen for the reception of the collodion film. The invariable pleas against the introduction of this system are:—"You cannot get operators to be careful enough. Dust, &c." Now really this is all humbug. Whosoever has skill enough to polish a plate can albumenize one, and if there is too much dust in your dark room (where the operation should be performed) to albumenize plates, I pity your negative bath. Albumenizing, according to the various plans usually published, is, I admit, a nuisance, but if you will follow my directions, the plan generally in use in America, you will not only find it free from difficulty, but will also reap these advantages:—1st. You will save *time*. With a little practice anyone can albumenize at double the rate of polishing. 2nd. You will save *money*, for by this system you can procure better negatives—chemically faultless—without a stain or pin-hole, if your bath be in order, on ordinary glass, which will cost you only a *trifle more than half* the price of best polished.

These advantages, together with all of those which naturally attend them, are of such importance that they must commend themselves to every photographic artist who reads this paper. Once more, gentlemen, do not be over conservative, give it a fair trial, and I guarantee that you will never more of free will have a polished plate in your establishments.

Take the yolk of one fresh egg. Put this in a wide-mouthed ten-ounce bottle together with some clean broken glass, and agitate until the albumen is well frothed. Fill the bottle with ordinary cistern water. Add from eight to ten drops of stronger water ammonia, and the solution is ready. No filtering is required. Keep a porcelain or

glass dish containing strong solution of commercial nitric acid and water, in which place overnight the prints required next day. When about to albumenize, set a smooth board beneath the tap in your dark room, and let a small stream of water run. Now take a plate, place it flat upon the board under the running water, and scrub it vigorously both sides with a small brush (one of those common wooden-backed nail-brushes, sold at sixpence, will answer admirably). When thoroughly cleansed, rinse well beneath the tap, and while wet flow the plate on the concave side (few plates are perfectly straight—ascertain the side by looking along one edge longwise) with the albumen solution. Then quickly rinse the back of the plate beneath the tap, and, turning it over, let one small wave of water run across the face—that albumenized. Now set it briskly in the rack, to let it drain and dry, and proceed to the next. When dry, stow them away in plate-boxes, and use as required. That is all.

I have given a full and somewhat lengthy description in order to ensure being understood. Analyse it, and you will find there is no trouble in it. Try it, and you will prove that it realizes all that has been promised for it.

The albumen solution keeps good as long as it smells of ammonia; if it grows faint, add more ammonia. But if there is any doubt as to whether it is good or not, throw it away, and make some fresh.

These plates, thus prepared, will keep very well for a few days; but if they are not required for immediate use, make the albumen solution as follows:—The yolk of one fresh egg, frothed as directed, to twenty ounces of water and ten drops of ammonia. Filter. Proceed as before, only after flowing the plate with the solution, set it *at once* in the rack, without either rinsing the back or flowing the face with water. When dry, pack them together with clean blotting-paper between each (albumenized sides all one way), in parcels of (say) twenty-five. Let the outer covering be stout brown paper. They will keep for months. Enough for summer use can be prepared during the slack winter season.

I will conclude this first paper by giving the formulæ of, perhaps, the best iron intensifier known. No fear of fogging, and in every way commendable. Of course, in America, we seldom need to have recourse to intensifying, except in the case of children and animals, and even then but seldom, the light being clear and good. But in England—or, let me say, London (for that has been England to me so far)—an intensifier is an absolute necessity in every photographic studio. Here it is. Try it:—

Saturated solution of iron	...	2 ounces
Citric acid	...	2 "
Distilled water	...	40 "

IS A LICENSE FOR CARBON PRINTING WORTH HAVING?

MR. A. HESLER, an experienced professional photographer in America, writes as follows to *Anthony's Bulletin*:—

I am constantly receiving letters with about the following questions, asked for me to answer; and it has occurred that I could best reply to all through the medium of your columns.

1. What do you think of the carbon processes as demonstrated and patented by Mons. Lambert?
2. Does he not give you the demonstrations before you pay the money? Did he do so in your case?
3. Is the process as well adapted to C.D.V. work as silver printing, and are the results better?
4. Can any man be master of the process after seeing it worked only once?
5. Does it not take from three to six months before a man can turn out first-class work?
6. Can it be worked successfully in warm weather?

7. Does it do away with so much retouching as Lambert claims?

8. Do not the Lambertype enlargements look spotted or blurred, as silver enlargements do?

9. Do you use it now for all styles of work in your gallery?

10. Is not the price asked exorbitant?

11. Will it pay in a country town of three thousand inhabitants?

12. Will you send me a sample print?

To which I now make reply:—

1. It is to me exceedingly interesting, and the results very beautiful.

2. I was given to understand that the pay was required in advance, and I took the hint and paid accordingly.

3. At the present price of material it costs more than silver prints; and, in a small way, a man cannot make as many card prints with the process as by silver printing. For strong negatives the results are better than silver; for weak negatives, not so good.

4. No man can be master of any process in our art by simply seeing it done once; but having seen it demonstrated by competent hands, a man may go on and master the process by himself, and his success will be according to his ability to excel in other branches of our art.

5. After two weeks' practice I made prints that were pronounced by competent judges in Philadelphia as the very best they had seen by the process.

6. I have not yet worked it in the hottest summer weather; but I keep my rooms at from 69 to 80°, and find no trouble on the score of heat.

7. Lambert is an expert at dodges, and, for enlargements, his plans effect a great saving of time; but for small work, the finer and more artistically the retouching is done, the better.

8. No.

9. No; not as direct or double transfers. It is at present too much trouble to make people appreciate the difference, and pay the advanced price over silver prints; but for porcelain or window transparencies, and for framing—left on the glass, not transferred, but backed up with the porcelain transfer paper, and delivered ready for framing—people will appreciate them and pay a good round price. I get from ten to fifty dollars each for such.

10. I am perfectly satisfied with the investment I made; but I believe very few who have invested have made the application of the process that I have.

11. It has paid me many times over already. The population of this town is about three thousand; but I got some customers who came up from the city, twelve miles away.

12. I cannot afford to send samples for nothing, but will do so to any one enclosing fifty cents, with the request.

In the above I simply give my experience as far as I have gone with the process.

THE PHOTO-LITHO. OIL PAINTING, OR CHROMOTYPE.

BY I. M. VAN WAGONER.*

TAKE an unmounted print, wet it, and brush over a solution of isinglass made in the proportion of one teaspoonful to half a cup of water; lay it on the glass and rub out all air-bubbles (the same as you would to make an old ivory-type), and let it dry. Now fill the glass that your plate is on with castor oil, letting it stand until it is perfectly transparent, which will take from three to twelve hours, according to the paper the photograph is on. When transparent, rub off all the oil from the picture, which is ready for painting. Now colour the eyes from behind the photo., and then lay it on a piece of white paper to see if you have the right shades (use a retouching frame to colour

the photograph on); next the hair, very lightly, then the jewellery; also all whites that you wish to make resemble lace or white work. Now put over the photograph, on the back, a second convex glass, and fasten the edges with sticking paper; now mix the flesh-colour and paint all over the face. Then paint over the hair, to make it the shade desired. Next comes the drapery: paint it over the same as you would the face, and you can get as beautiful, soft, and rich colour as you desire. When painted, back with white cardboard.

Some people use starch for mounting the photograph, and paraffin for making the picture transparent, which is the mineral process claimed by some to be permanent. The prices charged for colouring these pictures in the city are \$3 00 for C. D. V.; \$5 00 for Imperials, and \$10 00 for eight by tens.

Correspondence.

PROPOSED MEDALS OF PROGRESS.

SIR,—In your last issue, Mr. Walter Woodbury, referring to the proposed medal of progress, suggests that such awards should only be given for "published or patented processes." May I be permitted to suggest a closer limit, and urge that they should only be given for processes or discoveries freely published, and in no case to discoveries or things which have been patented? I do not wish to condemn the patenting of a discovery, but simply to point out that where a discoverer patents his novelty, he chooses his own form of reward; he hopes to receive a commercial recompense, and is in his perfect right in so doing. But he should be content with this, and content with the disqualification it involves in a contest for honours as well. That the process should be made public ought to be imperative in a contest for honours. In the case of M. Rousselon, I believe he got a medal for simply showing results, which might, for all the jury knew to the contrary, have been produced by some one else. If he had described the process, as I think he was bound to do, the method might probably have turned out to be that which Mr. Woodbury communicated to him.

March 2nd.

ARGUS.

UGHT PHOTOGRAPHERS TO UNDERSTAND CHEMISTRY?

MY DEAR SIR,—Will you allow me a space in your paper for a few words as regards the above heading: viz., Ought Photographers to Understand Chemistry? I have read in a book on photography—and it was one of the best—that a knowledge of chemistry was not needful to the photographer. But, in my opinion, the writer was quite wrong, and I think a knowledge of chemistry would be one of the greatest boons to the photographer (however slight his knowledge might be). Now I have no doubt that twenty photographers out of twenty-five have not the slightest knowledge of the chemicals they work with. The photographer of course knows that the iron developer is a reducing agent, but he may not know why! He knows it brings out the image—that's enough for him. Now I think if he knew a little more on the subject of chemistry he would not have half the troubles that beset the photographer. Another instance: Bath works perfectly, but for some reason it gives imperfect plates. The photographer who does not understand chemistry is at a loss to account for it. But if he understood chemistry he would be at once able to remedy the horrid bath. And so it would be in all his photographic occupations—if he understood chemistry the slightest bit in the world, he would have ten times less bother than he

* *Anthony's Bulletin*.

had when he knew no more about it than the man in the moon (but perhaps he may, so we will say a deal board).—
Yours truly,
C. R. F. VERNON.

Grafton, Underwood, Kettering, March 5th.

[There cannot be a moment's doubt, we think, as to the advantage of some knowledge of chemistry to a photographer. He should at least know something of the chemicals with which he works, and of the chemical reactions involved in the processes. It is true that without this he may carry out the operations in a mechanical sort of fashion; but an intelligent man will rarely be content with such a position. We have always strongly commended Captain Abney's Instruction in Photography because, in addition to a description of the operations, he at the same time describes the chemical reactions which take place in each.—ED.]

EDINBURGH PHOTOGRAPHIC EXHIBITION.

SIR,—Gentlemen who consent to act as judges at photographic exhibitions would not need to be thin-skinned, as no matter how eminently qualified they may be for the work, or how thoroughly to the satisfaction of the great majority, both of exhibitors and the general public, their duties may be discharged, they, apparently, must lay their account to be hauled over the coals by a discontented minority, each unit of which, confident in the superiority of its own judgment, does its little best to show up the failings of the greater men. To fair, open criticism there can, of course, be no objection, so long as the opinions expressed are based on known facts; but, as a rule, the critics to whom I allude give rein to their pens inversely in proportion to their acquaintance with the subject, and so convey a false impression to those who may be unacquainted with the circumstances.

We have an example of this—in a very mild form, it is true—in the letter of "One of the Visitors to the Edinburgh Photographic Exhibition." He seems altogether to have misapprehended the nature and scope of Mr. Macbeth's paper; but with that I do not care at present to bother your readers, and mean only to notice the concluding paragraph of his letter.

After a well-merited tribute to Mr. York and the valuable and beautiful lantern pictures with which his name has long been identified, he says, "I think, therefore, the judges would have done themselves honour in bestowing it" (whatever that may mean) "on that gentleman." I suppose I may presume that the "it" refers to the medal awarded to Mr. Ganz, of Brussels, and that "One of the Visitors, &c.," thinks it should have been given to Mr. York.

In the production of lantern pictures Mr. York is *facile princeps*, and by none are his works more highly admired than by the members of the Edinburgh Photographic Society, at whose popular evenings they have often played so conspicuous a part. But if "One of the Visitors, &c.," was also an observer, he will be aware that no medal was offered for lantern pictures—the wisdom of the omission is a different matter—and must have seen the beautiful series of large transparencies, about twenty-four by twenty, exhibited by Mons. Ganz, generally surrounded by numerous admirers, and, therefore, ought not to have confounded things that differ.—I am, &c.,
JOHN NICOL.

RAPID CARBON PRINTING.

DEAR SIR,—On reading the letter of Sir Thomas Parkyns, describing the extreme rapidity of the carbon printing process as practised by Mr. Witcomb, I was much puzzled to account for the slowness of my own method. Sir Thomas states that between five minutes past eleven and twelve minutes past twelve—that is to say, in sixty-seven minutes—he saw Mr. Witcomb print three portraits (one of which took $3\frac{1}{2}$ tints to expose) in carbon. In the time was

included every operation up to the finished result, during which they had to be dried slowly. I tried the experiment of putting out my actinometer, and printing three tints, and noting the time consumed—viz., one hour and thirty-five minutes; this on a moderately dull day.

Another matter I should be glad to get some information on is the best method of applying the transfer paper to the picture developed on the collodionised glass. My great difficulty is in getting the paper to accommodate itself to the high relief of the gelatine film, which, when dried, shows a number of glossy specks, particularly round the edges of ovals, &c.—I am, dear sir, yours, &c.,
H. W.

FRESH ALBUMEN.

DEAR SIR,—Respecting Mr. N. K. Cherrill's remarks on the above subject in your issue of the 23rd of February, I beg to remark that I have had at times over one hundred heads of poultry to try the difference between albumenized paper prepared from new laid eggs and that prepared from "good French eggs," but there was no difference in the results when using only the clear albumen from foreign eggs, and this is what I have been using of late years, guided by an experience of over eighteen years. Nevertheless, I shall be glad to know the results of Mr. N. K. Cherrill's experiments.—I remain, dear sir, yours faithfully,
ANTHONY RIVOT.

Willenden Green, N. W., March 7th.

Proceedings of Societies.

REPORT OF THE COUNCIL OF THE PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE proceedings of the Photographic Society of Great Britain for the past year have been characterized by a steady progress in the work which should be the real object of its existence—namely, the study and advancement of photographic art science by individual thought and collective deliberation; at the same time it must not be overlooked that the state of transition which some branches of photography are now experiencing must of necessity prevent much of that investigation into its strictly scientific aspect which might otherwise be undertaken, and limits the probabilities of making new discoveries, which is the part of this Society to afford its members opportunities to discuss.

As an example of a branch in a state of transition, we may instance the gradual departure from silver printing to the production of permanent photographs, which forces itself upon the attention of all who desire that "a thing of beauty should be a joy for ever." Such a change as this necessitates the individual photographer experimenting for himself in private, and hence he is not in a position to assist so much in the collective public work of a society, and thus it follows that the publication of new ideas, or any practical research, becomes vested in a comparatively few workers. Your Council cannot but express how much they feel the Society is indebted to those members who have, during the past year, laid before them some very important and valuable discoveries and investigations; and whilst stating this, they would still desire to remind any member who may have remarked anything that is new or different in his idea to what others have done—however small or apparently unimportant—that it almost becomes a duty to lay the same before his fellow members, so that fresh minds may be stirred up thereby to new efforts of research.

To meet the necessities of the time, your Council have considered the advisability of devoting some of the usual monthly meetings to a simple discussion upon various known subjects, upon which a paper, being more formal, might be found to be not so well adapted or necessary. The value of such evenings consists in many persons being able to make observations, arising from their previous individual knowledge, which is difficult, if not almost impossible, to be done when a paper is read upon a new subject. The experiment has already been tried upon one evening, and your Council has every reason to be gratified with the result; and to indulge in the hope, that when more properly understood, these discussions will become a most valuable phase of the Society's work.

Your Council must congratulate the Society upon the increased attendance which has taken place at all your meetings during the past year. The opportunity afforded for the inspection of the works of fine art in water colours which adorn the walls of their present place of meeting not only adds brilliancy to the gatherings, but, whilst affording examples of study, must greatly increase the pleasure of those present.

Fourteen papers have been read before the Society since last February, at eight meetings (including this evening) as follow:—"Further Researches respecting the Influence of Various Bromides on the Collodion Emulsion," by Leon Warnerke; "Note on the Production of Antimony Photographs," by John Spiller, F.C.S.; "On the Measurement of the Actinic Value of Sunlight," by Captain Abney, R.E., F.R.S.; "On the Preparation of Sensitive Dry Pellicle from Collodion and from Gelatine," by Colonel H. Stuart Wortley; "Note on a Dry Plate, exposed and developed Fifteen Years after its Exposure," by Wm. Brook (Bretford); "A Novel System of producing large Panoramic Negatives by Means of Ordinary Small Cameras and Lenses," by Leon Warnerke; "On some New Facts in Support of Dr. Vogel's Colour Theory," by Captain J. Waterhouse, F.R.A.S.; "Note on the New Nitrate of Lead and Ferricyanide of Potassium Intensifier," by Captain J. Waterhouse, F.R.A.S.; "Notes on a Tour in South Italy," by the Rev. W. A. Crofton Atkins; "On Stereoscopic Botanical Subjects," by F. H. Worsley Benson; "On Photographic Operations in the Recent Arctic Expedition," by Captain Abney, R.E., F.R.S.; "A New and Simple Method of Working in the Field," by Peter Mawdsley; "Note on the Reticulation of the Film in Carbon Printing," by H. Baden Pritchard, F.C.S.; "Photography from a Holiday-maker's Point of View," by H. Baden Pritchard, F.C.S.; and a Discussion at one meeting upon "Carbon Printing."

It is with feelings of regret that your Council feel called upon to record that the Annual Exhibition held during the past year was not so successful as might have been anticipated from the success attending the previous display, and, although it remained open for a longer period than any of the former exhibitions, the attendance was not in any way commensurate.

Your Council would also beg to remind the members of the Society that it is only by united strenuous efforts, in annually providing the various works for exhibition, that the progress of the Art-Sciences can be made known to the general public, and hence when any particular falling off in the character and number of the works exhibited is made evident, every individual member must, to some extent, feel the reaction arising from the reduced interest shown by the outside world. But your Council will take into consideration the causes which have led to this want of success, and consider the best means of securing, amongst other things, an exhibition of a more international character, in the coming season, and of enlisting in its support the practical aid of a wide circle of photographers.

The following analysis of the Exhibitions, made again this year by the Assistant Secretary, is appended, as a record of facts, which becomes desirable and interesting, if only from a statistical point of view:—"There were 78 exhibitors; of these 37 were members, and 41 non-members. Of these 78 exhibitors, 34 were from London and 44 from the country. Of the 37 members, 17 were from London and 20 from the country. Of the 34 London exhibitors, 17 were members and 17 non-members. Of the 44 country exhibitors, 20 were members and 24 non-members. 852 frames were hung; of these 189 contained 407 separate pictures of landscapes, architecture, animals, and flowers, and 163 frames, containing 584 separate pictures of art studies and portraits.

Amongst the 852 frames are included 53 containing enlargements, comprising 35 portraits and 18 landscapes and architectural subjects. In all, 941 separate photographs, besides 52 negatives and 40 transparencies.

In conclusion, your Council hope that the hearty co-operation of all the members of your Society will be given towards the advancement of both the scientific and art-side of photography, and that the forthcoming year may be rich in valuable communications, so that the prestige of the Photographic Society of Great Britain may be worthily sustained.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE usual meeting was held in the Room of the Society of Arts, on the evening of Thursday, the 1st instant, the Rev. F. F. SEATMAN, M.A., in the chair. The minutes having being read

and confirmed, the following gentlemen were duly elected members of the Society:—Messrs. F. D. Lavendar, C. Bennett, and W. Adkins.

Mr. W. Brooks then brought before the Society briefly some recent experiments he had recently made in connection with "Magneto-Photography" (see page 111). Some conversation followed; but in deference to a protest from Mr. Taylor, who remarked that until they had the subject properly before them it would be inopportune to open a subject which must lead to a protracted discussion, its further consideration was postponed, until Mr. Brooks was in a position to bring the subject before the Society in a completer form, when an evening would be devoted to the subject.

Mr. MAWDSLEY then read a paper on the subject of "Collodion-Bromide Emulsion" (see page 114). Some interesting specimens were handed round for inspection.

Mr. TAYLOR asked Mr. Mawdsley which form of collodion-bromide emulsion plates be considered the best substitute for wet plates in studio work.

Mr. MAWDSLEY thought the moist plates best, and they could be kept ready for use, as they would keep well for three weeks. Dry plates were not so sensitive as the moist. A dry plate was as quick as an ordinary wet plate, whilst the moist plate was three times quicker.

Mr. FOXLEY had tried the plan of converting a negative into a transparency by means of nitric acid, using a bath bromide plate, but failed to get density sufficient.

Mr. NEMERT said he had had a similar experience, but found out the cause and remedy. After using the nitric acid, the film was in such an acid state, even after washing, that it refused to intensify. He found it necessary to dose it with ammonia and water, so as to remove all acidity, and then the alkaline pyro intensified it readily. Over-exposure would also cause thinness.

Mr. MAWDSLEY thought that it was only with iodized plates that the thinness of solarisation from over-exposure occurred.

HENRY WARNERKE said as emulsion plates could be produced as sensitive as wet plates, and give equal delicacy and excellence of result, there could be no reason why they should not be used for portraiture in the studio.

After some further conversation,

Mr. Brooks remarked that he had found that the use of ale or albumen with the pyro aided in securing intensity.

A desultory conversational discussion was continued, in the course of which it was suggested that Mr. Mawdsley should prepare a paper on the best mode of using emulsion plates as a substitute for wet plates in the studio. This at a future period he promised to do.

The proceedings then terminated.

FRENCH PHOTOGRAPHIC SOCIETY.

A MEETING of this Society was held on the 2nd ult., M. DAVANNE in the chair.

M. J. B. JOHNSON was elected a member of the Society.

A letter was read from Count Kamarowski, requesting, as member, to be supplied with a diploma or certificate to that effect.

The PRESIDENT stated the Society had not hitherto granted diplomas to members, but as many of the latter were strangers he proposed to forward such applications to the Executive Committee, to be dealt with by that body.

A letter from M. Leon Vidal announced the publication of his year-book, the *Agenda Photographique*, for 1877.

M. H. J. NEWTON read a digest of the foreign journals.

M. BRAUX, of Dornach, forwarded to the Society some samples of carbon timus prepared by him, for the inspection of members. M. PENROT DE CHAUMEUX, in the name of M. Noel, exhibited a little furnace, or lamp, to employ with petroleum spirit, for use in ateliers unprovided with gas.

M. ZIMMER submitted to the Society a very fine and numerous collection of views of the East, printed in silver.

M. DAVANNE exhibited two specimens of photo-engraving, the delicacy of which demonstrated the progress which M. Rousselon has recently made in this branch of the art.

M. ANDRA read the report of the Committee of Awards for 1876-78. The decision of the Committee was to the effect that they could not do better than to bear testimony to the remarkable applications of photography made by M. Janssen, by awarding him the grand silver medal of the Society.

The Society having unanimously ratified the conclusion of the Council, the President took upon himself to remit the medal to M. Janssen.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—At the next meeting of this Society, on Tuesday, March 13th, at the Gallery, 5A, Pall Mall, East, the evening will be devoted to a discussion on "The Silver Bath." The subject will be introduced by Mr. John Spiller, F.C.S.

COPYRIGHT IN PHOTOGRAPHS.—The *Stationer* says, on this subject:—"Our attention has been called so frequently to this subject that a paragraph or two respecting it will, at least, be sure of pleasing many of our readers. Great dissatisfaction prevails among photographers by reason of certain firms advertising, for a very small sum a dozen, to reproduce and furnish good copies of all cartes forwarded to them. The photographer, from his point of view, argues that he has to exert himself to his utmost to press and light his sitter, in many instances to go to the expense of special backgrounds and the most optical appliances, and that after all this he is paid, generally, a few shillings for his 'specimen portrait,' the portrait is sent elsewhere for copies to be printed from it. It seems to us that it will be useless for the photographer to attempt to claim any copyright, but he may and can do this—charge as much for one copy as for a dozen, and so meet the case. Good manipulators will always command a fair price, and the skilled operator has the matter entirely in his own hands. The Act which passed in 1869 declares that 'the person making or executing the same shall not retain the copyright thereof, unless it be expressly reserved to him by agreement in writing, signed at or before the time of such sale or disposition by the vendor or assignee of such painting or drawing, or of such negative of a photograph, or by the person for or on whose behalf the same shall be made or executed; but the copyright shall belong to the vendor or consignee of such painting or drawing, or of such negative of photograph, or to the person for or in whose behalf the same shall have been made or executed.' This really reads that no copyright can be held by the photographer, unless given in writing by the person photographed."

CAUTION TO PROVINCIAL PHOTOGRAPHERS.—We find in a local paper, the *Lynn News*, the report of a case heard before the County Court at Lynn, which suggests a caution to provincial photographers in dealing with travellers. William Hoare, trading as Reeve and Hoare, stationers, of London, sued Edwin Bullock, of Lynn, photographer, for £4 3s. for goods supplied. The circumstances of the case were peculiar, and are these:—The plaintiffs had in their employ a traveller named Ramon, who called on the defendant soliciting orders. The defendant, believing that complainant solicited orders for himself only, gave him an order for goods amounting to something like £6, on the condition that the traveller bought something of him. The traveller bought a hundred views of Sandringham, &c., and the defendant paid him the difference in the account. The plaintiffs, however, subsequently sent an invoice of the ordered goods, and requested payment of the sum of money which had been paid in goods to the traveller. The defendant refused to recognize plaintiffs, but his Honour, while severely censuring the conduct of Ramon, ordered a verdict for the plaintiffs for the full amount, intimating that if the defendant did not own the plaintiffs in the matter, he ought to have sent the goods back at once; he also pointed out to the defendant that he had his remedy against Ramon.

CRACKING IN CARBON TISSUE.—For the benefit of the carbon workers, I will state that I use one ounce of glycerine to twenty of sensitizing solution; and the tissue dries without any danger of its getting hard and crackly, and therefore need not be watched. It will cut up and roll much easier (being more pliable). It is also rendered more sensitive thereby (about one-quarter), but there is no other effect.—*Anthony's Bulletin*.

To Correspondents

COLLODION.—We do not know of any place where you can buy specimen portraits, except such as are published because of the celebrity or interest attached to the person. No portraitist would or should feel at liberty to sell copies of the portraits of his private sitters. Your only plan is to take portraits for such a purpose. Remember also it would not be an honourable course to exhibit, as your own, portraits produced by others.

J. COAN.—We do not know of any lens suitable for the work you require, which we should recommend in preference to that you have. A portrait lens would, of course, be more rapid, but not so suitable to the work. That which you indicate as No. 6 might possibly answer better for groups. But you must remember that there is a limit to the rapidity of lenses under such circumstances, and short exposures must depend on the use of very sensitive plates. 2. Your prints appearing too brown when finished is generally the result of insufficient toning. You tone them a little deeper than you wish to appear when fixed, you say, but possibly will not sufficiently deep. But there is another frequent cause for the prints looking brown, dull, and poor, of which inexperienced photographers rarely take account. The fault is often in the negatives, which have not sufficient force to permit deep printing. Thin negatives, which print rapidly, often give such prints. To secure a rich well-toned print, it is necessary to have a brilliant negative, which permits a sufficiently deep deposit of silver in the blacks of the print before the light portions are overdone. Sometimes the defect arises from the quality of the paper. 3. You cannot have a better work than Mr. Robinson's "Pictorial Effect in Photography"; but we fear it is out of print at present. John Burnett's works on Composition and Light and Shade are excellent also.

TONOMANUS.—You are evidently labouring under the mistaken impression that increasing the strength of your iron developer will give you greater intensity in your negatives. The contrary is the fact. A strong developer will give more harmonious negatives, but with less intensity, than a weak developer. If you reduce your developer to half your usual strength, you will obtain greater contrasts. But the probable cause of your difficulty is the use of an over-acid bath. Boiling the bath generally leaves it more acid, and unless you neutralize the acid, it will have a tendency to give thin images. Neutralize with carbonate of soda, and try.

VALENTIN GUILLON.—The prints enclosed are very good examples of the kind of work. We see no reason to think that working photography in a carriage should be especially unhealthy, if you take care to keep it as well ventilated as possible, and the exercise you have in country roads, travelling with it, will go far to counteract any ill effects arising from the atmosphere of the operating carriage.

PHOTOFILM.—"Putty powder" is the best material with which to polish out scratches from glass, but it is a dangerous task to attempt this upon a lens, for if you alter the figure in removing the scratch, you may easily spoil your lens. Putty powder is made of us.

M. G. TOWNES.—The crystallization you describe in your negative films must probably arise from imperfect washing after fixing. You must remember that for its thorough removal a very thorough washing is required, especially in cold weather. You may use hypo which has fixed a few prints for fixing negatives, but it is possible that in doing this you may increase the intensity of your negatives by a deposit of sulphide of silver. The addition to the solution of a little boiled oil will make it less likely to crackle and scale, or the addition of a little collodion is often useful.

J. C. STANNING.—Thanks. We will obtain the *Builder*.

W. B.—The production of collodion positives has, for many years, been comparatively small, and hence few articles have been devoted to the subject. You will find one in our last YEAR-BOOK on page 72. Dr. Diamond will shortly restate some of his experiences on using the proto-nitrate developer. Here is a formula for its preparation: dissolve in GONNOR of water 319 grains of proto-sulphate of iron, and also dissolve in 6 ounces of water in another vessel 300 grains of nitrate of baryta. Mix the two solutions, and by filtration remove the sulphate of baryta formed by the double decomposition. The clear green liquid is solution of proto-nitrate of iron, and is ready for use in development.

A CONTINENTAL SUBSCRIBER.—We do not know of any copies of Turner, or the other modern English painters you name, published in carte size. We fear that we have no facilities, even if we could undertake the task, to enable us to indicate which of the landscape photographs of the English photographers of repute best illustrate the art principles indicated in Mr. Robinson's work. Mr. Lake Price's articles on Composition, &c., appeared in our third volume. We believe that lantern slides of Pinnel's Cave, Olant's Conway, &c., are published, but do not remember by whom. Write to Mr. F. York, of 87, Lancaster Road, Notting Hill, London, for his catalogue of slides. You may probably find them there. Some years ago there were published in Berlin a large series of card and other small sized photographs, containing copies of the great masters. The publishers were, if we remember rightly, Schaner and Co.

CARMINIST.—We have seen the *Notes and Queries* you mention. They are intended for private circulation, amongst themselves only.

CARBON PRINTING.—The conclusion of Mr. A. Walsley Turner's series of articles on this subject is in type, but stands over until our next through press of matter.

Several Correspondents in our next.

The Photographic News, March 16, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

FORGERIES OF BLUE AND RED BANK-NOTES—A PHOTOGRAPHIC PLOT.

Forgeries of Blue and Red Bank-notes.—Among the difficult problems which photographers have of late succeeded in solving may be cited two, which have for years past been deemed out of their power to accomplish. We allude to the counterfeiting of the blue bank-notes of France and the red ones of Scotland. A gentleman connected with a large Glasgow firm recently informed us that he had seen, pinned to a genuine Scotch note, an imitation which would have been passed unquestioned by all but professional tellers. Again, the news reaches us from Germany that the cobalt blue notes of the Bank of France are likewise imitated with considerable success—or, at any rate, reproduced in such a way that most people would be mistaken. Blue, and cobalt blue especially, as we all know, gives a very faint mark upon a negative, while red, on the other hand, especially if tinted with a little orange, produces the same effect almost as brown or black. Yet, by some means or another, methods have been devised for reproducing, by means of the camera, sufficient indication of these colours to prepare a printing block from which notes can be struck sufficiently like the original to pass muster. This, then, is the result of all the exertions which paper makers and printers have made to produce documents which cannot be photographed. In the case of the Bank of France a very expert and accomplished photographer (M. Gobert) has been for a long time attached to that establishment, and has afforded valuable services in connection with the detection of forgeries; while in this country there is scarcely a bank of importance which has not paid considerable attention to the matter of securing their papers from being tampered with by the camera. Twenty years ago the commercial world was particularly alive to the matter, and the colours employed to-day upon the various cheques were only adopted after very serious deliberation. Any colour, it was considered, would baffle the photographer, and the employment either of very actinic pigments or the reverse was but an additional safeguard. Now it would appear as if colour is rather an aid than a difficulty in the way of counterfeiting cheques and notes, for the pigment covers a multitude of minor errors which may exist, and by its presence at once suggests to the eye the genuineness of the document. It stamps the paper with a certain individuality, and if this is adequately represented in the forgery, few persons will look into details. In the case of the Bank of England notes and the Prussian notes, which are simply black and white, forgeries are by no means rife, although, in the case of the latter, the microscopic type, informing the world that those who are found guilty of forgery will be subject to penal servitude, has ceased to be the protection it was formerly, for microscopic type is of all things easy to produce by the aid of the camera. How the red and the blue can be successfully photographed is a subject we need scarcely enter into here, but that a clever operator could accomplish it there is little doubt. An Austrian gentleman (M. Max Jaffé), who has investigated the subject very fully, and has published an interesting report upon his conclusions, which we shall print at length in our next, points out several methods which a forger might adopt, although he does not deny that he would have in any case a difficult and tedious task before him. Thus a negative taken in the first instance of a cobalt blue note might show but little difference between the rendering of the white ground and the colour, but this difference may be exaggerated afterwards to any extent, M. Jaffé points out, by reproducing it by the aid of the dusting-on process, or by simply producing successive transparencies in the camera which are underexposed and well intensified. His suggestion is to employ

layers of colour printed one over another upon cheques which he believes will be more effectual than anything else in preventing any competition between the banks and the outside public in this branch of industry. Since the detection of the Scotch forgers in Glasgow some ten years ago, who employed photography very skilfully in their trade, there has been no particular case under the notice of our criminal courts. In that case, it may be remembered, the principal agent concerned (a man named Greatorox) was cleverly trapped in America, whither he had retired from active life. That he was in one of the great cities of the western republic was a fact pretty generally known, but to pick him out of the crowds of emigrants arriving from all parts was a task that gave little hope of success. A simple scheme, however, soon brought the fish to the net. An advertisement was put into the papers for a photographer and lithographer possessing certain qualifications which the forger was well known to have; and within the space of a few days the man who was "wanted" turned up in his own person to take the appointment that was waiting for him. The appointment, as he afterwards found out, was in England, and he held it, we believe, many years. However, photography is by no means the natural enemy to bankers that some people would make it out, for it has caused many an absconding clerk and defaulting cashier to be brought to justice. The reference we made, too, to the Bank of France shows that photography is regarded, by that establishment, at any rate, with confidence. Instances are not unfrequent of the detection of forgeries by means of the camera, for the sensitive plate sees matters in a different light to ourselves. An erasure, unapparent to the casual observer, is soon detected by the cliché, which prints a spot or stain where the surface of the paper has been abraded, and where it has ceased to reflect the light in the same uniform manner as the surrounding portions. Again, an ink mark which has been written over, or figures apparently obliterated, are often seen distinctly upon a photograph, and at the Bank of France it is, indeed, an admitted fact that the camera is one of the best and cleverest detectors of forgeries.

A Photographic Plot.—We do not remember to have seen photography figure as the turning point of a novel, although the art has occasionally been dragged into play and farce. But in the *Moniteur de la Photographie* there is an extract from an amusing story in which photography plays a most important part, and has much to do with the unfortunate denouement. A young gentleman, who is an amateur photographer, receives an invitation to the house of a gentleman whose acquaintance he is particularly desirous of cultivating, by reason of the existence of a charming Mademoiselle Clémence. The young fellow's doings as a photographer have reached the ears of father and daughter, and they both pray him to bring his apparatus and camera when he favours them with a visit at their chateau. M. Adrien, the young photographer, arrives, and is not long in ingratiating himself with the young lady. Time goes on, when at last, late in the afternoon, the question of taking a picture comes into the mind of the old gentleman. Adrien must bring out his camera at once, and begin forthwith. He is to take a group—one that is to be a reminiscence of their country life. A magnificent prize is to be included in the picture, to be posed in the vicinity of the proprietor, and Mademoiselle Clémence runs off to get a favourite rabbit. Adrien rather objects to the rabbit, but he is told, as his brethren have many a time before him, that it is the quietest and most obedient of animals, and the charming girl will hold it in her arms to prevent its moving. The young amateur poses the group with the eye of an artist, and, in the midst of a good deal of bustle and much impatience on the part of the other guests, Adrien takes his photograph. The result is, as might be expected, the ox and the rabbit all over the plate, the first obscuring the father, and the other the daughter. A good

deal of laughter over the picture ensues, only Clémence and her papa do not join in the merriment. They do not care to be made the subject of practical joking, and look glum enough upon M. Adrien and his apparatus. The latter is glad enough to withdraw quietly, but in his nervousness manages to upset both iron developer and silver bath—the first upon an inlaid floor, and the other upon the train of a gorgeous widow. The curtain falls upon the young man's ignominious flight, and the destruction of his cherished hopes.

FRENCH CORRESPONDENCE.

ALCOHOL IN CARBON PRINTING; ITS EMPLOYMENT IN THE SENSITIZING BATH—EXTENSION OF PHOTO-MECHANICAL PRINTING IN PARIS—WOODBURYTYPE AT THE "MONITEUR UNIVERSEL" OFFICE—THE "AGENDA PHOTOGRAPHIQUE"—DAVANNE'S "ANNUAIRE"—IMPROVED SULPHATE OF COPPER DEVELOPER.

No doubt your readers remember that some months back M. Leon Vidal published a note in reference to carbon printing, in which he pointed out that a sheet of tissue might be exposed under a negative for a much less period if, after printing, it is put into alcohol and allowed to dry before development. M. Boivin has taken this communication as the starting point of a series of experiments, and has recognised many advantages in the employment of alcohol in connection with manipulations in the carbon process. He has been led to compose a new sensitizing bath, which he thinks will render very great services, for it permits him to obtain, he says, results much superior to those secured by the sensitizing solutions now in use. He prepares it in the manner following:—

Spring water	70 cub. cents.
Ordinary alcohol	30 "
Bichromate of ammonia	3 grammes
Ammonia	1 to 3 drops

The bath is tested for slight acidity by means of litmus paper. As rainwater contains organic matter of a kind to reduce the salts of chromium, and thus to destroy the solubility of the mixture, it is preferable to employ spring water in making up the bath. The salts which spring water contains do not alter in any way the solubility of the bichromated gelatine; or, at the most, they have a tendency to lower the strength of the bath. An immersion of from one to two minutes of the tissue is quite sufficient for sensitizing it. It moistens, and all greasiness disappears without undergoing any contraction, as in the case of baths without alcohol, especially if the immersion is too prolonged. The sole inconvenience of the bath is that it is a little more costly, although an ounce or two of alcohol does not, after all, represent a very great outlay, even at the price charged for it in France. When the tissue comes out of the bath, it is placed, film downwards, upon a well-cleaned glass plate, and the squeegee is passed over it to remove the excess of liquid. The sheet is then detached from the glass, and is suspended to dry. It is necessary to be very careful to employ in this operation a special squeegee, for if touched with any alum the film becomes insoluble. Emanations from a laboratory, such as gas, benzole, &c., are also injurious. Bichromate of ammonia imparts much less sensitiveness than bichromate of potash, but the liquid retains its virtue longer. With alcohol, the activity of the first of these salts becomes much greater than that of bichromate of potash mixed with water. In conclusion, M. Boivin thus resumes the advantages gained by the addition of alcohol to the sensitizing bath: the drying of the tissue is much more rapid; it is effected in a few hours, instead of requiring a whole day; in the printing, about one-third of the time is gained, and the image is more vigorous. The solubility of the tissue remains the same for a much longer time, especially if the tissue, in a well-dried condition, is put

between two glasses somewhere sheltered from light and moisture. For this reason, it is well to put the sensitized tissue into boxes, hermetically sealed, which contain chloride of calcium. Finally, the action of alcohol prevents the tissue from contracting, as in the case with an ordinary bath. The constriction takes place in the interior of the tissue itself, and produces a slight degree of coagulation, which does not, however, affect the solubility of the gelatine in warm water when proceeding to development.

An important addition is being made to the photo-chromic workshops and greasy-ink printing works at the office of the *Moniteur Universel*. It is the fitting up of a workroom for photoglyptique or Woodbury printing. There are twelve presses of large dimensions, which furnish double pictures in the same fashion as is done at the establishment of MM. Goupil at Asnières. As a matter of course, the hydraulic press necessary for the production of the clichés—or, rather, printing blocks—is of considerable power. Already M. Leon Vidal has made several experiments, of a novel and ingenious character, towards applying the new process. We believe, in fact, that he will shortly show the results of his work, so useful from an industrial point of view, which will be as interesting as they are unexpected. Something is said, too, of the development in France, very shortly, of the process of printing by platinum introduced by Mr. Willis, and which has been acquired by MM. Wittman et Poulenc. Many photographers who have witnessed the manipulations connected with the new process say great things of it.

The *Agenda Photographique* for 1877—M. Leon Vidal's Annual—appeared this week. It contains several very successful prints in greasy ink and photochromie.

M. Davanne, on his part, has just published, not a continuation of his *Annuaire*, which he has abandoned since the war, but a veritable practical Manual of Photography, in which is to be found all the new methods which represent recent progress in our art. This volume, which is in a very condensed form, and gives details in a terse and precise manner, represents the present condition of photography from a practical point of view, and embraces all the improvements produced within the last few years.

I have just received from one of our principal experimenters a very exhaustive note upon the employment of a developer which is not absolutely new, but which seems to have been forgotten. The formula for its preparation is as under:—

Water	125 cub. centimetres
Sulphate of iron	6 grammes
Sulphate of copper	2-50 "
Acetic acid	8 cub. centimetres
Alcohol	5 "
Ammonia	A few drops.

When this solution, after standing, is filtered, it may be preserved for several days, but it is, nevertheless, well to employ it before it is very old. To develop the image, there is poured into a glass the necessary quantity of liquid, and a few drops of a saturated solution of acetate of lead in distilled water is then added, to which a little nitric acid has been put. I have in my hands several portraits taken with an exposure of ten seconds in an apartment lighted by a single window, and which owe to this method of development excellent modelling and great vigour. Probably the readers of the PHOTOGRAPHIC NEWS may be interested enough to undertake some experiments with this particular developer.

ERNEST LACAN.

OUT-DOOR MEETINGS.

BY JAMES CRIGHTON.*

MR. CHAIRMAN AND GENTLEMEN.—It is with some diffidence that I appear before you with a "paper," seeing that I am, comparatively speaking, but a young member

* Read before the Edinburgh Photographic Society.

of this Society, and also that my knowledge of photography is of such a very limited nature, having attained to little more than in being able to prepare a decent plate, and develop out of it a fairish negative; and, believe me, I am not a bit conceited in having got so far, for the longer I prosecute the, to me, pleasurable pastime, the more I find I have to learn; and the oftener I mix with the working members of our Society, the further I get advanced in the art. This is the principal reason I have for doing my little to advocate out-door meetings, for at them many useful hints are got, and much experience gained. And another reason I have for bringing these meetings before your notice is the fact that there are many who have joined the Society within a few months do not know of the existence of such an auxiliary; and there are also those who have been connected with it for years who seem either not to know, or have forgotten, that these meetings have been an institution for long. It is by way of information to the former, of remembrance to the latter, and for the purpose of having them more largely taken advantage of, that I endeavour to bring their claims before you.

Our out-door meetings were, I understand, instituted some years ago for the purpose of making up for, in some measure, the recess of our ordinary meetings during the summer months, it being often found that an accumulation of business waiting for the resumption of the usual meetings was the result; but by the institution of outdoor meetings any pressing business could be disposed of. Now this, I believe, was one of the objects to be gained; but never, in all my experience, has it been the principal one. I have never sat in council at any that I have attended. I have seen lots of cameras employed, and heard a deal of conversation about the Society, and the weal thereof, but little more in the way of business. These meetings are composed of members who, for the occasion, are willing to leave the conducting of their business to other heads and hands, and enjoy a day in the country.

A day having been fixed on, and the spot to be visited selected, a general preparation takes place. Those who have not a stock of plates on hand, get this state of matters rectified. Others get their traps collected together—everything carefully gone over to see that all the apparatus is in its place, and all working smoothly, for it's a bad job if you omit to put your lens in your pocket, or forget your tripod head, or find that that fractious shutter is going to bother you again, and you are far removed from where a sprinkling of black-lead or other suitable substance can be got to sweeten its ups and downs. This brings to my recollection what frequently happened to a friend of mine, who eschewed collar studs, on a Sunday morning (when a long lie was excusable); it was no unfrequent thing to hear him exclaim, when his collar button and collar button-holes did not work sweetly, "It all depends on a button whether or not I am to get to church this morning." Just so it is with photography in the field: on that fractious shutter, or the forgetting of that very particular screw, will depend whether or not I am to get some of those charming views, or, at all events, get them in comfort. I speak from experience as to the preparation I used to have in my early days, but I am happy to say that as to forgetting any requisite, I speak only from surmise. The plan which I have adopted for some time, and the motto which suits it, is "Ready, aye ready." I have everything at all times ready, that is to say, my slides are always full, camera, &c., packed up, everything just to lift and go, and this plan I would recommend to all who are in the habit of leaving everything to the last, for it is strange if, in the hurry of the moment, something is not forgotten.

Well, then, after a pleasant drive, run, or sail, we arrive at the scene of our operations, or, at least, the locality in which our work is to lie. Here we may have the rushing torrent, or peaceful, flowing stream or river, the hill and dale, the stately trees, or venerable ruins,

which, while furnishing us with subjects for camera, give us also subjects for contemplation, and lead our minds "far back to other years."

If the immediate locality abounds in subjects, a tour of inspection takes place, and the time fixed when this and the other view will be suitably illuminated; if, on the other hand, they are so situated as that the mode of procedure is rendered impracticable, then things are just to be taken as we find them, and the best selection possible made. Cameras are then unpacked, set up, and focussed, light and watch (about the best of all actinometers) consulted, and, under favourable circumstances, in from three to five minutes we expect to have a fine picture.

Now during our journey hither the conversation has been almost entirely on photography; it has brought us out, and it is the topic and object of the day. Are we bowling along some beautiful highway? We see a picture in that quaint gateway, from which there recedes an avenue of noble trees; in that lovely, rose clad cottage, with its latticed windows and rustic porch. Is our home, for the time, on the deep? Then the rolling billows, as they break on some rock-bound coast, arrest our eye. Or are we careering through a beautiful tract of country, getting only a momentary glance of the beauties we pass? Yet, almost instinctively, we see down in that glen with its streamlet and wooded banks, in that silvery lake with the bold and rugged mountain side mirrored on its bosom, something worthy of our admiration. So identified does everything appear to be with our pursuits, that we find pictures in trees, beauties in running brooks, subjects in stones, and photography in everything. And then the experiences of one another are freely given, and this and the other method of working is recommended, new processes are sifted, anything striking in apparatus is overhauled, and a chorus of voices extol its merits: "It's a capital idea!" says one. "The description given leads me to think that it will be a felt want supplied," says another. But one canny Scot thinks that "it looks all very well in print, but the proof of the puddin' is the presein' o't." Photographic literature generally is considered, and this and the other doctrine therein taught. Thus the conversation proceeds, and thereby much valuable information is got. And during our picture seeking, how our minds and tastes get elevated (bear in mind I am speaking as a young aspirant in the art)! With lynx eyes we watch the every motion of the veterans who, as a rule, figure among us; we see how carefully they study the composition of a picture, and how fastidious in their choice of subjects; whatever advice they give is the correct thing; in short, they are our model, we pin our faith in photography on them; so, ye veterans, beware! ye are the hope of the rising generation.

I come now to a few suggestions I have to offer in regard to our out-door meetings. I would suggest that these should be more frequent than hitherto. We should aim at having, at least, six during the season—one every month, beginning in April; that a day be fixed on which the same should be held; that the work done during the season be submitted to a suitable party outside the Society, who would adjudicate thereon; that a prize of some sort be given to those which, in his opinion, possess the most merit, but that no one be permitted to compete who has not attended at least three of the meetings, and who has not six pictures to show; and that all those who purpose attending should send their names to the Secretary, who would intimate to such the time and place as they occur. I think it highly desirable that we should begin early. It becomes a very slow process when these meetings are delayed so long, and held when the light gets so poor, and the weather so unsettled—when it requires nearly, and in some cases a whole, hour's exposure to be of any use. It is also, I think, very desirable that some such award as I have indicated should be given, for thereby an impetus would be given in the way of a little friendly rivalry, which would induce a

better attendance, and help to ensure some good work being done. It is equally desirable that a definite time be fixed, which would enable us the better to make our arrangements to attend.

I have thus endeavoured to bring before you something absent our out-door meetings, and my aim throughout has been to show the advantages that may be derived from them in thus associating with the members of this Society who attend. As to advantages, we have had line upon line in the charming work—charming alike for picturesque effect and manipulative skill, which it was a high privilege to view in our late exhibition—work which the eye never tired of beholding, but which unfolded fresh beauties by continued inspection—notably so in that frame of "Picturesque England and Ireland"—and which should give such an impetus to us all, that some good work will be the result in this and succeeding years.

CARBON PRINTING.

BY A. WELLESLEY TURNER.*

In order to simplify my description of the development of the latent image, which we must now suppose is impressed on the tissue, and at the same time to make it as practically comprehensible as possible to my readers, I must say a few passing words on the developing sink in which this operation is performed. I wish it to be understood that I do not give it so much as a model for others to copy, but rather to facilitate my description of that branch of the operation for which it is used. I merely state what I have found most useful in my own circumstances; others must suit themselves as most convenient, remembering that it is more important, first, to properly understand all the operations necessary for the production of a certain result, and then make for themselves such appliances as most expedient, than to go by any fixed system of fixing up the operating room.

I develop my prints in the same room as I wax and collodionize my plates, the opposite side of the room being occupied by the developing sink, which is merely a large wooden tank, lined with lead, about seven or eight feet long by three feet across, and six inches or so deep. At one corner of this is a waste pipe, and over it a second bottom, made of pieces of wood, running the whole length of the sink, each piece about six inches wide, with space of an inch between them; this is raised a little from the bottom of the sink, and forms a clean flat place to work on, as well as allowing a free use of water, without fear of slopping. At the left end of the sink is the before mentioned dish for washing the collodionized plates, and at the other end a similar dish for use in the development. Next to the latter is a flat zinc tray 22 by 26, and further on a flat board for squeegeeing on; at the back of the sink a stand for holding the plates when washing after development, and at each end a tap for supply of cold water, with two or three feet of flexible tubing attached. My supply of warm water is obtained from one of Maughan's patent geysers, conveniently fixed to the wall near the developing tray. This is a capital apparatus for obtaining a supply of warm water, and gives quite sufficient to supply any ordinary business for this purpose. With this slight outline of what we are to work with, we will now commence the operation of

Development.—Previous to commencing this, arrange your prints in quantities sufficient to fill each plate; partly fill the flat zinc tray with cold water, and taking one of the washed collodionized plates, lay it on the squeegeeing board; place as many of the prints as are required to fill one plate in the cold water, draw them briskly through two or three times to free from air-bubbles, and gently pass a soft sponge over the surface to clear off any adhe-

ring particles of dust or dirt; leave them here till they have absorbed sufficient water, which they will have done when they become very limp, and are flat in the water without curling up in either direction; do not hurry this part, but, on the other hand, it is very important not to leave them in too long, so if this should be done they will refuse to adhere properly to the plates without a great deal of squeegeeing, and require to be left long under pressure. There is a right time for doing this as well as all other things, and when this arrives, take the prints out one by one, and place in position on the wet collodionized plate in a manner similar to mounting silver prints; this should be done rapidly, so that they may, as near as possible, be equally soaked; a piece of india-rubber cloth is now thrown over them, and they are well squeegeed. The prints are all treated in this manner, and placed in the space kept for the purpose on the bench, one upon the other with a sheet of stout blotting-paper between each; upon the whole a sheet of plate glass is put, and they are left under pressure for about twenty minutes. Beginners, I am afraid, are rather inclined to shorten this period in their haste to see their work. The operator need not be idle whilst they are under pressure, for he will find a variety of things to do in the interval. I only use one flat dish for developing my small prints, the one before mentioned; while waiting, this can be emptied of the first water used in washing, and filled again with warm water; the vertical dish can also be filled, as well as many other useful and necessary preparations for the next step in the operations. If they are taken from under pressure too soon, it will be found that they do not adhere as well to the plates during development as they should, and consequently will not bear much rough usage, and are even liable to come up at the corners, although this seldom happens in developing upon collodion unless the tissue is defective, or they have been left a very short time indeed under pressure. When left the full time you will find that the action of suction which secures the image to the plate has done its work perfectly, and it is then much safer to work them; it is perfectly remarkable in some cases how firm the adhesion secured by this means is; twenty minutes, as stated before, is sufficient time, however, to secure this effect, but they may be safely left a much longer period. On several occasions, when pressed for time in the evening, and being unable to develop that night, I have left them under pressure till the next morning, taking the precaution, however, to leave wet blotting-paper between each plate in contact with the back of the tissue to keep it damp, and then have finished them the next morning, without the slightest deterioration in any respect; so long as the tissue is kept moist there is no fear, although, if dry, of course the printing would have continued by the long keeping, much to its detriment. This fact may be useful in cases when it is necessary to print till the last thing, or other business calls you away.

(To be continued.)

CARBON PHOTOGRAPHY.

BY AD. BRAUN AND CO.

[M. BRAUN was one of Mr. Swan's earliest licensees, and has, during many years of extensive practice, acquired a large and valuable experience in working carbon.—Ed.]

We offer to the photographic public a simple and practical description of the different operations constituting the carbon process, as used in our ateliers, after thirteen years experience. This treatise, which we have endeavoured to make very explicit, will contribute, we hope, to the spread and adoption of a process which offers to photographers so many important advantages.

The inalterability, the artistic aspect of carbon photography, the simplicity of its manipulations (outside of the manufacture of the prepared paper), will cause this beautiful process to be used in all photographic establishments in the

near future. We use daily in our establishments about twenty-five rolls of 4 metres by 85 centimetres (157 inches by 33½ inches). We are prepared to deliver to the trade as many as one thousand rolls per day. This proves that we have surmounted many difficulties to make this process very practical.

It is the result of all these efforts and of a long experience that we offer, and we do it with a confidence given to us by the favour which the public accords to the products of our house.

INTRODUCTION.

The carbon process has for basis the property possessed by gelatine mixed with a salt of chrome (such as the bichromate of potash) of becoming insoluble when acted on by light. If, therefore, colouring matters are incorporated with this gelatine, they will be retained, after exposure to the light, by the portions of the gelatine which have become insoluble, or will leave their support together with the parts that have remained soluble, accordingly as they have been differently impressed by the light. The gelatine mixed with colouring matter is spread upon a paper support; in this state it is not sensitive to light, and can be preserved for an indefinite length of time. To make it sensitive, it suffices to impregnate it with a solution of bichromate of potash.

In the sensitized state the paper thus prepared cannot be kept so long; it is necessary, therefore, to only prepare the quantity we wish to use. The image given by the exposure is hardly visible. It is developed by washing the soluble portions in warm water, after having placed it on a new support.

To better describe this operation, we will trace an enlarged section of this pigmented paper after exposure. The gelatine which has been made insoluble is at A A; it is the image; B B is the coating that has remained soluble. If, therefore, we were to immediately wash the paper in warm water, the gelatine which has remained soluble would in

Fig. 3.

dissolving carry away with it the image. It is, therefore, necessary that this image, which comprises the insoluble portions, should be placed on a support before proceeding to the washing. The pellicle attaches itself to this new support, and abandons in the washing the soluble gelatine and the primitive paper. The image is developed. This image by this first transfer is naturally reversed. It is necessary, if a reverse negative has not been used, to make a second and final transfer.

The brilliant appearance of the print depends on the surface of the support which has served for the washing. This support must be chosen in accordance with our desire to obtain a print more or less brilliant, or even mat. All these different transfer papers are prepared and furnished by our house. The consist of:—1st. Papers for direct transfer (prints obtained with reversed negatives). 2nd. Temporary paper supports (caoutchouc and waxed papers) for direct negatives, the prints of which are to be transferred to (3rd) final papers.

After this rapid summary of the general principles of carbon printing, we will successively examine the different operations of the process that we follow in our establishment, and which consist of:—1st. Sensitizing and drying. 2nd. Exposure to light. 3rd. Transfer, direct and temporary. 4th. Washing. 5th. Final transfer from the temporary support. 6th. Varnishing.

1. *Sensitizing and drying.*—Immerse the sheet of prepared paper in a filtered bath of a solution of bichromate of potash contained in a porcelain dish. Allow it to remain until the pigmented surface is softened, withdraw it, and

place it, the gelatine, underneath, upon a glass plate slightly inclined on the dish (fig. 2).

Fig. 2.

Pass a caoutchouc squeegee over the back of the gelatinized sheet, so as to remove the excess of bichromate solution, which will flow into the dish; then remove the sheet, and suspend it, by wooden clamps, upon a thin cord stretched for the purpose. In very dry weather it becomes necessary to place at the lower extremity of the sheet a strip of light wood, so as to prevent the curling of the sheet, which in drying would break. The proportions of the bichromate bath may vary according to the degree of sensitiveness which it is desirable to give to the paper. A weak bath gives a less sensitive paper, but the prints of which give more depth. A strong bath, on the contrary, produces greater sensitiveness, but less vigour. These effects are produced within an average of from four to five per cent. of bichromate.

The sensitizer should have an alkaline tendency, acid in the bath being always injurious. The bath should, therefore, be composed as follows:—

Water	1 litre, 1 quart
Bichromate	50 grammes, 13 drs.
Ammonia of commerce	10 154 grs

Up to the present time the paper is not sensitive even after its immersion in the bichromate bath. This operation may, therefore, be done in daylight. A necessary precaution is to perform this operation in a cool place, especially in summer, in order to avoid the too great softening of the gelatine coating. The temperature of the room should not exceed 15° Centigrade (59° Fahr.).

The manner of drying exercises also an influence on the sensibility of the paper, and should be done regularly, and, as far as possible, in six or eight hours, in a dry place, well ventilated, at an average temperature of from 10° to 20° Centigrade (50° to 68° Fahr.) at most, and in complete obscurity.

2. *Exposure to Light.*—The time of exposure appears at first to offer great difficulties to the operator, for the appearance of the prints can only be judged after the washing; notwithstanding that, a little practice and the aid of our photometer will soon enable one to work with absolute certainty. The paper should be dry enough to be slightly brittle.

Printing may be done in the sun or in the shade, observing, however, that, contrary to what takes place with albumenized paper, carbon prints made in the sun are more vigorous than those that have been exposed in the shade.

To judge of the time of exposure, it is necessary to observe the strength of the cliché, the condition of the light, the sensitiveness of the paper. To obtain the greatest amount of vigour, the paper should be sensitized in a weak bath, and printed in the sun.

In the contrary case, a stronger bath should be used, and the printing done in the shade. It is absolutely necessary that clichés used in carbon printing should be surrounded by opaque borders.

PRINTING PHOTOGRAPHS ON GLASS.—M. Siegwart, in the *Polytechnisches Journal*, directs the operator first of all to secure an image by means of gum, honey, &c., and bichromate of potash, and to dust this hygroscopic picture with red lead powder. The red lead image is then burnt in; and the more soluble lead glass thus obtained is treated with concentrated nitric acid whereby a dull, white image is produced which may be viewed as a transparency.

THE DISCUSSION ON THE SILVER BATH.

It is probably unfair, and obviously unwise, to expect any very especially new information to be elicited during an organized discussion of such an old subject as the silver bath, its defects and remedies. The silver bath, with its varying conditions, forms such an important feature in the everyday life of a photographer, and the means of inter-communication between photographers are so facile, that every novelty, every incident, and every suggestion in connection with the bath has probably been made and fully discussed long ago. And still, as many photographers will be ready to exclaim, there are many puzzling, some almost mysterious, aspects of the question which have not yet been solved, and which were not solved on Tuesday night. The one point prominently brought under the attention of photographers, with which they were not thoroughly familiar before, was the frequency of sulphate of silver as a cause of pinholes. As Mr. Spiller pointed out, the source of this contamination is not difficult to suggest. In every sample of iodide of potassium he examined he found sulphate of potash as an impurity. Traces of sulphuric acid often remain in contact with pyroxyline. Much of the nitrate of silver used by photographers has been recovered from their residues, and most invariably contain traces of some sulphur compound. And, as we may add, it not unfrequently happens that commercial samples of nitrate of silver contain traces of sulphate, sulphuric acid having been used in separating the silver. The addition of a barium salt to the bath so contaminated at once proves a remedy, and eliminates the sulphuric acid as sulphate of baryta. It may be desirable here to mention, for the benefit of our younger readers, the fact that a powerful affinity exists between sulphuric acid and barium, so that where that acid exists, either free or in combination, it may as a rule be detected and isolated by means of a barium salt, which is thrown down as an insoluble white salt, sulphate of baryta.

The action of sulphate of silver as a cause of pinholes, and of the addition to the bath of nitrate of barium as a remedy, are not new facts, as Mr. Spiller observed, referring to us personally as his authority. In our issue for February 23rd, 1866, an article by Dr. Vogel appeared, entitled "On a New Cause of Pinholes and Streaks, and on the Action of Nitrate of Baryta in the Negative Bath." In this article the whole subject is fully treated, the origin of the sulphate of silver being traced, and the action of the barium salt as a remedy described; its tendency to give increased intensity being especially noted. It is to be regretted that the details of exhaustive experiments of this kind are so often overlooked or forgotten. Scarcely

any one seems to remember Dr. Vogel's discovery. Two or three years ago a member of the South London Society proposed the addition of nitrate of baryta to the bath as an empirical remedy for pinholes, without propounding any theory of its operation; and it has, during the last few years, acquired some vogue as a remedy, whilst few who have benefited by its use have ever associated Dr. Vogel's name with the benefit. The frequency with which it has proved efficacious shows how common the defects arising out of the presence of sulphate of silver in the silver solution have been.

Another remedy for a disordered bath, essentially of an empirical character, is cyanide of potassium, regarding the value of which there was much testimony forthcoming on Tuesday evening. As Mr. Payne, of Aylesbury, pointed out, he wrote to us many years ago mentioning the accidental addition of cyanide to his bath, which, however, turned out to be beneficial. So far as we remember, the first person to propose the use of cyanide as a valuable remedy for a disordered bath was Mr. J. S. Tulley, then, we believe, of Sheffield, and now of London. This is something like fifteen years ago. He added a teaspoonful of his cyanide fixing bath to a negative bath, which looked like pea-soup, and, *presto!* he had secured a silver solution giving better results than when it was new. Mr. Blanchard was able to confirm the claims of cyanide as a remedy. Mr. H. J. Burton, a photographer of unusual skill and experience, used cyanide to the original bath as conferring special qualities of excellence.

In some former experiments, Herr Warnerke had discovered fulminating silver in the precipitates, causing pinholes, but his experience had not been repeated by others. No light was thrown on many abnormal cases which have been recorded—such as the sudden appearance of a crop of pinholes, and their sudden and unexplained disappearance. The discussion will, however, be renewed at the next meeting of the Society, to be held on the evening of Easter Tuesday, and it is probable that the subject may then receive a more exhaustive treatment.

MR. SWAN'S DISCOVERIES IN THE CARBON PROCESS.

THE time is past in this country when it is necessary to maintain Mr. Swan's claims in connection with the carbon process. In the United States it seems, however, that Mr. Swan's patent stands in the way of introducing free trade in his process, and it becomes worth while to endeavour to undermine his claims. M. Adolphe Ott, as agent of M. Braun and Co., is endeavouring to introduce carbon printing, and supply the materials for the work; and to clear his ground, Mr. Swan's, and doubtless subsequent patents, must be proved invalid. We should scarcely think it necessary to repeat a defence of Mr. Swan's claims, which we have, on former occasions, showed to be sound and valid, but for one circumstance: M. Ott refers to us as evidence against Mr. Swan. This we feel bound to correct. He refers to our work on Pigment Printing, to establish a position precisely opposite to that which is in the work itself set down. In the passage referred to we had just been describing the details of Mr. Swan's process, and the history of its discovery and publication, and we proceed to remark that in the discussion which followed its publication, it transpired that Mr. Davies, of Edinburgh, had made transferred carbon prints in the course of some experiments as early as 1862, but the publication of this fact did not occur until after the patenting and publication of Mr. Swan's discoveries. As M. Ott and others must know well, the point upon which opposition to a patent must rest is prior publication: the question of prior discovery does not, therefore, come under discussion. Mr. Swan has never told the public when he made his discoveries. Their date, so far as the public is concerned, is that of their

publication. But we may mention that nearly twelve months before the date of publication we were aware, from personal information, that his discoveries had been made; how long before that we cannot state.

SUBSTITUTES FOR GLASS IN DRY PLATES.

IN Mr. Ellerbeck's interesting paper before a recent meeting of the Liverpool Society, he refers to certain difficulties he found in the use of paper as a basis for the collodion film. We are indebted to Col. Stuart Wortley for the suggestion that this was doubtless due to the omission of the *couche* of india-rubber, which should be placed between the paper and the gelatine. As this is a direction in which it is probable dry photography will tend, we think it will be interesting to reproduce here Col. Wortley's instructions published in our last YEAR-BOOK for producing negative tissue, as they are brief and practical, and have been found successful:—

"During the past summer I have obtained some very good negatives by the following method. Paper is coated with a solution of india-rubber in chloroform, and, when dry, with a twenty-grain solution of Nelson's opaque gelatine. When the latter is dry, the paper is ironed perfectly flat, and the edges turned up to form a tray. It is then coated with washed emulsion and dried.

"After exposure it is developed, either by use of a dish with false bottom, as suggested by Mr. Warnerke, or by the simpler method of forming it into a tray by turning up the edges.

"After development, the negative (having been thoroughly washed) is laid, collodion side downwards, on a piece of papier minéral, coated with gelatine rendered insoluble with chrome alum, and gently squeezed in contact with it. It is then floated, back downwards, on warm water, to loosen the negative from the first paper by dissolving the gelatine; and you then have a collodion film attached to the papier minéral, and ready for printing.

"This way of working gave me two advantages. I was able to use a thick paper, in some experiments even cardboard, as the original support of the film, while the finished negative was on papier minéral, ready for printing, and in the best state for any necessary retouching. I may mention that if preferred, the negative may be allowed to dry, and be transferred at any time subsequently to its development, and that if it is desired to reverse the negative, it can be floated off the original support, and then taken on to the papier minéral, so as to have either side that may be desired next to that paper.

"The above process was published by me in the journals more than two years ago, and I have found its great value since in the reduction of my impediments in travelling."

THE CARBON CONTROVERSY IN AMERICA.

OUR readers are aware that the carbon crusade against silver printing in America has produced a large amount of excitement in the United States. M. Lambert, as the *Cœur de Lion* of the crusade, has been very successful, and secured many staunch followers. But there are, on the other hand, some very virulent opponents. Our Philadelphia contemporary and M. Lambert have in some way come into antagonism, and the journal of the former has become the fortress of the unbelievers. Mr. E. Z. Webster, one of the fathers of photography in the States, makes a serious onslaught on carbon. He says very plainly to the carbon workers, "We Argentumites intend to foil your efforts to poison the minds of the public, and 'bulldoze' us into giving up the advantage which we have, for an untried, unproved, unprofitable, and, as yet, unpopular process." He boldly claims all the advantages for silver, and tabulates them as bearing relation as follows:—

	Silver.	Carbon.
1st. Softness and delicacy	10	8
2nd. Simplicity of manipulation	10	5
3rd. Uniformity of results	10	5
4th. Economy of production	10	7
5th. Indestructibility	10	6
6th. Permanency	8	8
	58	39

An old photographer at our elbow, as we write, suggests the addition of a seventh item to represent the relation of the writer in question to the two processes:—

	Silver.	Carbon.
7th. Knowledge and experience	50	1

Coming fairly for juxtaposition with this is the testimony in the same journal of Mr. Frank Rowell, the oldest carbon worker in the States. He says:—

"Now allow me to say this: If I had to make a choice, either change my business or go back to silver printing for my enlargements, copies, or any work that I say to my patrons is permanent, and that I am giving them an equivalent for their money, I would make a change at once. Now a word to my brother photographers. If your experience is like my own you will meet any number of people who come to sit to you for a negative. They are to have a crayon portrait, and the artist wants an outline. They do not want a photograph, they fade or turn yellow, and a free-hand drawing can be had (life-size) for twenty-five dollars. They may not be quite as good a likeness as a photograph, but it is permanent. That is about the kind of talk we hear in Boston.

"What I have been trying for years to do is to show work that has all the good points of a photograph, and the permanency of a crayon drawing, or a painting in oil colours. When we all show the kind of work mentioned, photography will have taken a long step from where it is now, and our patrons will not say 'Yes, it is beautiful, but they will fade in time.'

"Now a word about carbon work in hot weather. In the hottest weather of the last two years, besides our own portrait work, we have done two jobs for book illustrations, one of seven thousand and one of three thousand prints, and the failures were not three per cent. Would you have made less failures in silver than we did in carbon? In dull, dark weather we have printed twenty prints from one negative, while in silver the most we could have done would have been four or five prints.

"In my opinion the man or boy who has an opportunity to practise carbon printing, and neglects to do so, stands in his own light, and fearfully so, too.

"In my opinion, the photographer who makes large work from life or copies, finishing the same in crayon or India-ink, and does not print the same in carbon, makes the worst mistake he ever made if he intends to do a portrait business for the next ten years. The opinions expressed are not spasmodic or brought on by M. Lambert or any other parties, but from years of study and experiment.

"I bought M. Lambert's patents, and while he was at our place of business I learned enough to pay the license fee, if the patents are not worth the paper they are written upon. To meet a man who has struggled through the same difficulties you have had, and exchange thoughts and ideas, is often meat and drink to a hungry mind. For one, I am satisfied with the amount received."

VIOLET LIGHT—A HOME WRINKLE.

BY J. CHAMPION BRADSHAW.

I CANNOT refrain from adding my mite to the controversy which has been taking place upon the above subject for so long, half of which is, I think, at any rate, lost time. Although I think our photographic papers have been

giving us rather too much American news lately, yet I must say that I agree with the *Scientific American*, quoted in your last issue, wherein it states that light which has passed through violet glass is in nowise different from white light, only reduced in power. But I have thought for some time that this knowledge might be made very serviceable.

I have no doubt that the majority of photographers have had complaints from certain sitters that "the light was too brilliant," that "it made them feel inclined to shut their eyes, or frown." Now, if this is due to the yellow rays—and I think it is—it would be a very easy matter to have a number of squares of violet glass set in a movable frame underneath the usual glass roof of the studio; and whenever a sitter of this sort had to be operated upon, to move the violet glass to any portion of the studio required, which frame could be moved out of the way when done with. Try it, as our transatlantic wrinkler says.

By-the-way, those wrinkles were amusing, and go to prove that "there is nothing new under the sun," not even that "wrinkle" for copying prints through glass. I have known that to be in general use for the last twelve or fifteen years; but it may have been in use longer. I am but a young man. And the other "wrinkle," for albumenizing plates, I believe has been in general use for a year or two; at any rate, it has been so among the photographers I have the pleasure of knowing. Still I have no doubt there are many people who do not know these things even yet, and therefore their publication in your columns will give them another chance, undoubtedly. As the writer says, "they are very simple." I hope the transatlantic papers will copy.

Correspondence.

MEDALS AT EXHIBITIONS.

SIR,—Unquestionably some good or definite result is achieved by exhibitors when medals are awarded to the most meritorious.

Now, in regard to the last exhibition in Pall Mall, what reward, comfort, or satisfaction was given to anyone? Much trouble, time, and some expense were incurred in preparing and sending the various specimens; and, at the closing of the exhibition, each exhibitor might ask himself, what good have I received? There might have been a little just criticism, but some unfair, some injudicious, some foolish *à la* "the largest circulation in the world." Entire satisfaction to anyone there was none.

The man who sent work of inferior sort could say, like him who sent better, "I exhibited at Pall Mall." They both, so far, stand on a dead level. An annual exhibition of photographs is distinctly different to such an exhibition of pictures as the Royal Academy. Artists who send to the latter have a defined purpose, and expect a definite result.

Realize the idea of an annual exhibition of pictures where artists have no power of selling their exhibits, but must rest content with the faint comfort gleaned from the criticisms of the press! I imagine if that were made the rule of the Royal Academy, the hanging committee, at the time of the next intended exhibition, would have no pictures to hang at all.

The motives of an artist sending his pictures there are, firstly, that they should be admired, and lastly, that they should be sold. Photographers, like artists—I should say photographic artists—like painters, are made up of flesh and blood and bone and sinew, and have the same ambition, desires, and weakness for the substantial. Therefore, if you hold out to them a prize—one that is tangible, that they can see and feel—they will gird up their loins, enter the arena, and go in to win. If you offer a medal, you offer an inducement, a greater number will exhibit, and those who do will be sure to aim high.

But there is yet a matter I would speak upon in regard to the question of medals. There are some of us who do not wait until we can earn or deserve them; and it is this which will make the winning of them "not worth the candle." I allude to photographers exhibiting in their windows medals awarded to other men, and bought from them. One case I could point to where four medals are mounted on velvet, framed and exhibited, and I could tell the source from whence they came. Supposing at the late Edinburgh Exhibition, for instance, I had awarded to me a medal for real and intrinsic merit, and, with pardonable pride, placed it in my window, and my business was situated in the same street as that of the man with the four medals not won by himself. The public, not knowing the two circumstances, would say, "Ah! Signor So-and-So is four to one against you." Why, I should be tempted to throw my medal into the sea.—
TOM DOW.

RAPIDITY IN CARBON PRINTING.

SIR,—I detest having to answer anonymous correspondents. I like to know who it is to whom I am to give information—which I am always most happy to do, if I can—or with whom I am to wage battle.

I am quite a novice, and cannot, therefore, be an instructor in the case of the Lambertype process. However, in my capacity as a juvenile boxer, "H. W." has given me a grand opening to learn how to hit hard in the dark. I do not see my adversary, but I know he is there, and is apparently destitute of science. So here goes.

Can "H. W." read? If so, why does he say "five minutes past eleven," when he can see, plainly printed, in your issue of the 2nd inst., "five minutes to eleven"? Again, he says "sixty-seven minutes," whereas it ought evidently to be seventy-seven minutes, or one hour and seventeen minutes. Again, quoting me, he says, "he saw Mr. Witcomb print three portraits (one of which took three and a-half tints to expose) in carbon," &c. If he or any one else will refer to the same letter, he will find that I said nothing of the sort. I said that these portraits (negatives) were taken *before* the operations commenced on my own two negatives, which were the subjects of trial, and were not ready to be exposed at the same time. If I may repeat, I said, "I saw my own negatives" (not the portraits) "put into the pressure frames," &c. I do not think anything could be clearer.

Again, can "H. W." be a licensee of the Lambertype and chromotype processes? If not, no wonder he is in darkness, and it is not likely that he will be enlightened until he has purchased his full license.

Referring again to "H. W.'s" last clause, has he read Mr. Witcomb's letter in one of your previous issues (I think about December 1st or 8th), in which he gives full information about his queries? It is clear to me, having had only one lesson, so to say, that "H. W." knows nothing about it, and if he does not read a little better and more carefully, he will not get on with his manipulations, and he had better go to the Autotype Company to be taught. Mr. Witcomb is prepared to prove, any day, that he can repeat what he did in my presence before any witnesses. The best plan would be for "H. W.," if he doubts my statement, to bring one or more of his own negatives (as I did), see it put into the pressure frame, and then await the result. If he gave the negative into Mr. Witcomb's hands about noon, he might possibly have time to order and eat his luncheon before he found a print ready for him.

I believe Mr. Witcomb will shortly reveal something more astonishing than anything he has hitherto done.

If "H. W." is only an Autotype licensee, he cannot expect to know or be informed of the perfected processes.—
I am, dear sir, yours very truly,
THOS. PARKES.

PS.—I must for the future decline answering any letter from anonymous correspondents.

I forward you (if you will accept it) a fellow copy of one of the prints done in one hour and seventeen minutes.—
Harrham Cliff, Salisbury, March 10th. T. P.
[The print forwarded is in every way a perfect one.—Ed.]

COLOUR OF CARBON PRINTS.

Sta.—There have been unmistakable indications of late of the aim to produce a curious and monstrous kind of monopoly. The licensees of M. Lambert seem to arrogate to themselves the especial right not simply to use the patents for which they have paid, but the exclusive right to the best information as to the successful practice of carbon printing. Most of them are chary of communicating information, and, what is worse, they are indignant when men of liberal heart, despising this petty exclusiveness, do publish information. There has, I am informed, been a monthly journal established for the especial advantage of these licensees, to be circulated amongst them privately! And I must confess that I am astonished beyond measure that the Autotype Company should lend themselves to such a short-sighted narrowness. It must be to their advantage to extend the practice of carbon printing; whilst this step is manifestly calculated, if it is not absolutely intended, to restrict its practice.

It appears to me that the chromotypists have certain defined privileges with which they should be content. They have the right to use Lambert's patents, whatever these may be, and, if the patents are good, there need be no secrecy; and they have the right to be supplied with a special tissue. My object just now is to urge upon all carbon printers who are not of the Lambert type ring to avoid all resemblance to the colour especially, affected in "chromotypy." Leave it to the exclusive ring. The colour is not really good in any sense, and would never be selected by an artist as the colour in which to produce a monochrome. The reason for its selection, so far as I can see, is its resemblance to the colour of a gold-toned silver print, a colour which has received currency in photography not because it is the most artistic as a monochrome, but because it was the most pleasing tint which could be uniformly obtained in the ordinary process of silver printing. I do not remember ever to have seen a monochrome painted in that colour by an artist who had his pigments to select. Sepia, bistre, and indian-ink are the colours usually employed, and occasionally red chalk for portraits.

Would it not be much better to produce carbon prints in a rich brown, or a rich warm black? These are colours available to all, without trenching on the colour which is assumed to belong to the Lambert type licensees. The Autotype Company could have no difficulty in supplying tissue of such colour; nor could any of the manufacturers of whom rumour speaks as about to commence the supply of tissue, now that the patent for its manufacture is about to expire.

Let me, in conclusion, thank Mr. A. Wallesey Turner, Mr. Witcomb, and the other writers in your columns who have freely communicated their experience, disregarding the petty narrow spirit of others, some of whom have of late loudly paraded their liberality.—Yours,

A CARBON WORKER.

HEALTH OF PHOTOGRAPHERS.

DEAR MR. EDITOR.—Do I look like a man in poor health? Look upon this picture (I now send you), then upon that which is drawn in the News of January 26th, under the title of "Health of Photographers." Is it within the bounds of supposition, I ask you, that I could not get away with a plate of good old English roast beef, and a slice of plum pudding thrown in? If you think so, just order them to be set before me, and then judge for yourself the probal state of my health! And all this from a practical operator who has spent at least a score years in the dark room, and gone through every phase

of the business for thirty-six long years. Since my initiation into the mysteries of the Daguerreotype, I suppose I have inhaled enough mercury to make a shining mirror for others to reflect from, and if it could be possible for a chemist to extract the chemicals and compounds that have made acquaintance with the interior of my dark-room, he might get enough ether, alcohol, cyanide, iodine, gold, silver, bichloride of mercury, bromides and chlorides, acids, and other chemicals of minor note, to open a small stock depôt at a small cost. I admit, a practical operator is apt to get his fill of such things, if he is not very careful, that might over-develop him; yet there is such a thing as neutralizing the bad effects of such compounds by seeing to the ventilation of the dark-room, and having it in such a position as that the fresh air can at all times have access to it. The photographic gallery, especially the dark room, is not the most desirable place to keep the system healthy; yet, with a little care and attention, you may keep in as good condition as regards health, as in almost any other business. A few hints from me with your permission, may not be out of place to young heads, or even to some older ones.

First, always have a window in your dark-room, if at all possible, that opens out into the air. I have seen many dark-rooms with light admitted through windows into the skylight or operating rooms. Such rooms are always unhealthy, and, in time, will break down the best and strongest constitution of any operator. Fresh air is the most important point to be gained to secure health and retain it. Next, never mix your chemicals in your dark-room if they will admit of being mixed out of it. Never let the current or draught of air in your dark-room strike any of your chemicals before it does yourself. For instance: how often have I seen operators coat their plates holding them up between themselves and the light, little thinking by that means the draught from the window caused them to inhale the poisonous vapours of the collodion! Another bad practice is cleaning the fingers with cyanide between the light and the sink; even if the window is not open, the fumes generate through the room, which is slow death to the inhaler, and often produces that sickly feeling at the stomach and dizziness in the head which nearly all experience who use it. I have been there.* After handling cyanide, or cleaning the hands with it, rinse them off with a little of your iron developer, and it will neutralize any of the traces of cyanide that may be left on your hands. Leave your dark-room window open at night, both winter and summer—a little in winter will do—so that the poisonous fumes of the chemicals will be neutralized by morning. Never leave lumps of cyanide lying round your dark room. Keep all your chemical bottles tightly corked, and keep none in your dark room except what you really need. Make a practice of mopping, wiping, or sprinkling your dark room occasionally, as it will tend to purify it. Never take a nap in your dark room by any means. Exercise in the open air as much as possible after working hours, even if you are tired (that is, those who are confined very much in day time); it will tend to refresh the system. In summer, if at all practicable, and your pocket can stand the pressure, take a respite for a month from the cares of business—and you do not know (those who have not tried it) how good you will feel even if it be but for a few days—and, take my word for it, many of you will be healthy, fat, and jolly, as I am now at just threescore years of age. So

* During one of our excursions to a country town in the middle of summer we were planning up a 16 by 17 negative plate with cyan de. The dark room was small, and we don't recollect how many degrees the thermometer was from zero, but the first thing we did recollect was, Mr. Cyanide floured us, and if Mr. Developer had not been handy, most likely we should have not been here to relate this little anecdote, and the tanned Mr. O. and I had between themselves with our humble self; but our anecdote happened to be at hand to see fair play, and after the first knock down we began to develop that we had something for dinner. The assistance of Dr. Cyanide was called in, and he elevated us again; after that we looked more to our old friend Hyge for support. In developing negatives he has never floured us, and we intend to stick to him in the future.

see to it, ere it be too late, for health is the greatest boon of our life; when we have that we enjoy all things else in proportion, even to following and practising the beautiful art of catching shadows ere they fade.—Most respectfully,
J. H. FITZGIBBON.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE usual monthly meeting was held on the evening of the 13th inst., in the Water Colour Gallery, Pall Mall. Mr. J. GLAISNER, F.R.S., occupied the chair. The minutes of a previous meeting were read and confirmed.

Mr. SPILLER then read a brief paper to open the discussion upon the Nitrate Bath: its Defects, and the Remedies. He described the results he had obtained from examining the precipitates forwarded to him by Mr. York and Mr. H. J. Burton, of the Autotype Company. The latter gentleman always added cyanide of potassium to his bath; he found cyanide of silver in the deposits. Besides the iodide and bromide of silver, which he had expected to find precipitated from supersaturated baths, he had also found sulphate of silver. The presence of this salt, as a cause of pinholes, explained the action of the remedy proposed by Mr. Henderson, which proved effective. He must not omit to mention that he had ascertained, in conversation with Mr. Wharton Simpson since he arrived this evening, that Dr. Hermann Vogel originally proposed this remedy, which, of course, wherever sulphate of silver was present, would prove efficient. Sulphur doubtless found its way into the nitrate bath from various sources, the chief of which was probably the impurity of the iodide of potash used in the collodion, sulphate of potash being a common impurity. The nitrate of silver used by photographers was often made from reduced residues, which would almost invariably contain traces of sulphur. He had not found fulminating silver in the precipitates, as Mr. Warnerke had done, nor had he found oxalates, or other salts of silver.

Mr. WHARTON SIMPSON, in answer to the Chairman, said that he did not remember any details of importance beyond the fact that Dr. Vogel had, about ten years ago, suggested the use of a baryta salt as a cure for pinholes.

COL. STUART WORTLEY was unable to be present, but sent the following remarks, which he had intended to have made:—"The bottle I produce before you to-night contains an ethereal solution of nitrate of uranium, which has been exposed for a short time to the action of light. The action of light upon this solution throws down a deposit of urano-uranic oxide, leaving the supernatant liquid in the proper state either to be added direct to the collodion, or, after the salt has been crystallized thereout, the salt will be in a fit state for adding to the nitrate bath. I will not trouble you with unnecessary chemical details, and will therefore simply state that if commercial nitrate of uranium is added to the silver bath, the bath is injured rather than improved, while if the purified salt is added a considerable increase of sensitiveness is the immediate result. It will be remembered that when I first proposed the addition of nitrate of uranium to the silver bath for wet work, it unfortunately attracted the attention of a photographer who made trial of the process in ignorance of the qualities of the salt with which he was working, and also, apparently, in ignorance that both Herr Wortley and myself had pointed out the necessity of purifying the commercial salt previous to using it. The photographer in question added the commercial salt direct to his bath; hence his failure to appreciate the value of nitrate of uranium added to the ordinary silver bath. Fortunately, however, Mr. Peters and other gentlemen approached the subject, bringing to bear upon it the knowledge and thought that were not shown in the work of the before-mentioned photographer, and a record of their success having been published in the PHOTOGRAPHIC NEWS, the process is now gradually coming into use, and from many letters that I have received appears to be looked upon with favour. This may probably be a good opportunity to call attention to a subject which frequently crops up in photographic discussions, namely, the relative sensitiveness of the wet and dry processes; and as I have made a very large number of comparative experiments on this point during the past few years, I think I am in a position to give an opinion on the matter. We see sometimes statements that certain dry processes are two and even three times as sensitive as the wet, but I have never been able to confirm such a statement. On the contrary, though a dry plate can be made slightly more sensitive than a

wet plate, as prepared by the ordinary processes in use, if an extra sensitive wet process is used, such as a heavily bromized collodion, sensitized in a uranium and silver bath, the dry plate can no longer keep up its superiority. It would in my opinion be most interesting were the Photographic Society to appoint a committee to investigate this subject of relative sensitiveness. It would of course be necessary to keep to published processes, as it would not be of interest to the general body of members for secret formulae to be brought into the competition.

Mr. WM. BEDFORD asked if there was any wisdom in using nitrate of baryta. Until its use had become somewhat common such heavy deposits in the nitrate bath were unknown. He had prepared some nitrate from reduced silver residues, and by selecting the largest of the first crop of crystals he thought he avoided sulphate of silver.

Mr. S. G. PAYNE, of Aylesbury, said Mr. Spiller had referred to the use of cyanide in the silver bath as a comparative novelty. He remembered that something like twelve years ago he accidentally added some cyanide, with beneficial results. Mr. Wharton Simpson would doubtless remember that he sent him the details at the time, and that he replied that an accidental or empirical addition of the kind not unfrequently proved useful, even where no theoretical explanation seemed applicable. Mr. Payne went on to describe a case in which a bronze penny accidentally fell into the bath, which, however, after filtering, worked admirably.

Mr. SAWYER said as the able gentleman referred to by Mr. Spiller was not present, he would, in his name, as well as for himself, make one or two remarks. In their experience at the Autotype Works, pinholes were always the result of those small crystals visibly present, and which were doubtless crystals of sulphate of silver, or some other salt of silver which should not be there. Sometimes they found that simple filtration would remove these crystals, but not for long. He had an impression that their origin was often the presence of sulphuric acid in imperfectly washed pyroxyline; and thought that if a salt of barium—say the chloride—were added to the last washing water used when the pyroxyline was made, that this would prevent the formation of crystals of sulphate in the bath. As regarded cyanide, they always used it in the bath, believing it gave better results when so treated. In making a bath, they used common tap water. To this they added about one-tenth of its bulk of old bath solution, and exposed the whole to light and air. They then added nitrate of silver to make up the strength, and sufficient pure recrystallized cyanide of potassium to produce a slight cloudiness. It did not need iodizing, for it contained a portion of old bath. Of course old solutions would still accumulate on their hands, and these they evaporated and recrystallized, and carefully washed the crystals. Baryta had not proved useful in their hands. On the whole, they found the nitrate bath easy to make, and not difficult to keep in order.

Mr. BLANCHARD felt it right to say that as he was with Mr. Peters when the experiments were made with uranium in the bath, it did not increase sensitiveness, as Col. Wortley thought; it rather retarded; but it did improve the colour of the negatives. Regarding the nitrate bath generally, he had great faith in simple water and nitrate of silver without anything else. He detailed an experiment in which he improvised a new bath of simple water and nitrate of silver to work against a bath treated by a secret process which was offered for sale. His simple bath proved much the best. Mr. Taylor and Mr. Wharton Simpson were both present, and could bear testimony to the fact.

Mr. WROGE said he had no intention of speaking, but as he was referred to by Col. Wortley as an ignorant photographer, he would simply remark that, having tried the Colonel's suggestion, he published the details exactly as they occurred. He was subsequently told that he should have tried, especially, purified nitrate of uranium, and had done so, and found no increased sensitiveness whatever.

Mr. ENGLAND, like Mr. Blanchard, had great faith in simple water and silver. He liked to sun the solution after it was mixed, as he generally found that this eliminated some trace of impurity which had been present.

Captain ABNEY said that his name had often been mentioned in connection with the wretched uranium controversy. He had used it in the bath, but found no advantage in it for the wet process; but in the dry process it undoubtedly gave greater sensitiveness. Regarding sulphate of silver, he feared that sulphuric acid left in the pyroxyline was not uncommon. Wherever the deep brown colour was struck as soon as the collodion was mixed, it was probably due to this acid.

Mr. WROGE knew nothing of the effect of uranium in dry plates.

It was solely in relation to its effect in the wet process that he had reported.

Mr. YORK read a paper describing his experiences with pin-holes.

After some conversational remarks on fulminating silver,

Mr. SPILLER, replying to Mr. Payne's question, said that the action of the penny on the silver solution would be to throw down some metallic silver, and form a little nitrate of copper; and it was possible that if a bath were in a condition having a tendency to fog this might improve it.

A GENTLEMAN who had spent some time in New Zealand narrated some experiences. He had at times been able to get no nitrate of silver but ordinary caustic, and had got good work. He preferred water from a granite rock to make the silver bath with when he could get it.

The CHAIRMAN referred to the advantages of rain-water after the first shower had cleansed the atmosphere. He then proposed that the thanks of the meeting should be given to Mr. England, the Autotype Company, Mr. Bedford, Mrs. Payne, and others, for their contributions towards covering the walls of the room. The pictures of the water-colour artists having been removed left the walls bare-looking, and a number of members had contributed pictures to obviate this. The president, Mr. Glaisher, had sent fifty very fine large prints of ferns, which he had produced twenty years ago. These were fine prints, and in excellent condition.

Captain VERNEY was proceeding to propose that an album should be kept for Society pictures, when

The CHAIRMAN intimated that no motion of the kind was admissible at an ordinary meeting. A letter should be sent to the council.

The proceedings then terminated, the Chairman calling especial attention to the fact that the next meeting would be on the first Tuesday, not the second Tuesday, in the month. The meeting would be on the evening of April 3rd, Easter Tuesday.

EDINBURGH PHOTOGRAPHIC SOCIETY.

AN ordinary meeting of this Society was held in the Hall, 5, St. Andrew Square, on Wednesday evening, the 7th inst., Mr. LESSLE, President, in the chair.

The minutes of the previous meeting were read and approved, and Messrs. James Forbes, Crooke, John Crichton, W. B. Mitchell, Archibald Robertson, Purves, and Kirk were admitted ordinary members.

Mr. JAMES CRIGHTON then read a paper entitled "Our Out-door Meetings" (see page 122).

Mr. W. NEILSON said he had listened to the paper with much pleasure. He had some experience of the out-door meetings, and thought they were a feature of the Society that should be encouraged as much as possible, and nothing left undone that would draw out the members. He noticed that those meetings were intended to take the place of certain of the ordinary meetings during the summer months, and would like to know if it was the custom to transact business at such meetings, as if so, it might be that matters of much importance would be decided by a comparatively small number of the members of the Society.

Dr. NICOL replied that for a number of years it had been the custom of the members at the out-door meetings to constitute themselves into an ordinary meeting, and transact any business that might require attending to; but with the exception of the election of candidates for membership, almost nothing else was ever done. He thought it might in the future, as it had in the past, be safely left to the good sense of the members who were in the habit of attending such meetings, to do only such business as might turn up that could not be allowed to be over till October.

Mr. DOBBIE had always found a difficulty in finding suitable places at which to hold the out-door meetings, and thought it would be well if the members generally would send suggestions to the committee to assist them in making arrangements. Unfortunately for himself, his business engagements prevented him getting to as many of those meetings as he would like, but from his experience of those he had attended he could assure the members that they were very enjoyable.

Dr. THOMPSON was very glad that Mr. Crichton had brought forward the question of out-door meetings at the beginning of the season, as he was sure that members only required to be induced to attend one to secure their presence at all. It was no doubt a matter of importance to select suitable places of meeting, and equally important to have arranged as far as possible the order in which the pictures should be taken, as, generally speaking, there was some particular hour at which each view could be

better photographed than at any other. If the out-door committee could previously visit the ground, and arrange as to time and place, much valuable time might be saved.

Mr. SINCLAIR highly approved of the proposed method of increasing the interest attached to the out-door meetings, and gave notice that at the next ordinary meeting he would propose that an award be offered for the best pictures taken at such meetings, and that it be remitted to the council to consider and report as to how the arrangement should be carried out.

Dr. NICOL gave notice that at the next meeting he would move that a medal be offered for the best paper that should be read before the Society during the current year.

A number of prints contributed by Messrs. Nimmo and Son were then ballotted for, and the President intimated that at the next meeting Mr. Rodger, of St. Andrew's, would read a paper, and give practical illustration of the platinotype process.

Votes of thanks were given to Mr. Crichton and Messrs. Nimmo and Son, and the meeting adjourned.

WEST RIDING OF YORKSHIRE PHOTOGRAPHIC SOCIETY.

AN ordinary meeting of this Society was held at the Odd Fellows' Hall, Bradford, on Monday, the 5th inst., Mr. E. WORMALD in the chair.

The minutes of the previous meeting having been read and confirmed, the following gentlemen were elected members of the Society:—Mr. Doar, Bradford; Messrs. J. W. Sykes and Jno. Garrett, Dewsbury; and Messrs. L. Abell and Turner, Leeds.

Mr. A. CRABTREE then gave a lantern exhibition, using a pair of the newest lanterns out. A good assortment of slides was shown, comprising Continental, American, Irish, and a few, by some of the members, of Yorkshire scenery.

A vote of thanks was given to Mr. Crabtree for his entertainment, and the meeting then adjourned.

MANCHESTER PHOTOGRAPHIC SOCIETY.

A SOCIAL meeting of this Society was held on Thursday evening, the 8th inst., when about fifty members and friends partook of an excellent "knife-and-fork" tea. In the absence of the President through domestic affliction, Mr. THOMAS HEYWOOD, Vice-President, occupied the chair.

After the routine business had been disposed of,

Mr. W. T. CHADWICK exhibited and described a new form of oxygen generator (in our next). He also exhibited some charming little views by Mr. Woodbury from emulsion negatives, and mounted by Mr. Woodbury's new corner pieces on a large card. These views were greatly admired, and the method of mounting generally commended.

Mr. FRANKLAND exhibited several of Mr. Wendel Holmes' stereoscopes, which were quite new to some of the gentlemen present.

The walls were adorned by ten large (about twenty-four by nineteen) pictures from wet collodion negatives, by Mr. Wormald, of Leeds—very fine and perfect specimens of large work, and which excited considerable interest. The walls were also embellished by a number of Mr. Coote's well-known excellent pictures.

The meeting then adjourned to the lantern room, where Mr. Chadwick had a pair of Mr. Woodbury's lime light sciopicons, and exhibited a large number of fine views kindly sent by Mr. F. York, of London, for the occasion. Several dozens of pictures by members of the Society were also shown.

A vote of thanks was passed to Messrs. Chadwick, Wormald, Woodbury, Frankland, and Coote, and one of the most enjoyable meetings the Society ever held was adjourned.

Talk in the Studio.

CATALOGUE OF APPARATUS.—We have been favoured by Messrs. Watson and Sons, of High Holborn, with a copy of their newly issued catalogue of photographic apparatus, which contains an unusually large stock of lenses by the best makers at reasonable prices, as well as cameras and other photographic appliances. Photographers wishing to extend their stock of apparatus will do well to consult this catalogue before purchasing.

PHOTOGRAPHIC REPRODUCTION OF BANK-NOTES.—Photographers are certainly very clever people. The most recent feat that they seem to have successfully accomplished is the reproduction of the blue notes of the Bank of France and the red ones of some of the Scotch banks. Both red and blue have

The Photographic News, March 28, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

Sketches of Fancy, and Photographs of Fact.—"She is exactly like her photograph," said a lady at the theatre in the next stall to our own, who had been gazing for some time at H.R.H. the Princess of Wales, through a large double-barrelled instrument. We think the lady was a bit disappointed, on the whole, for she had come, as we overheard her saying, for the express purpose of seeing Her Royal Highness, and there was really nothing to look at, beyond what a photograph in the album at home had shown her. The amiable face of the Princess we have seen so frequently depicted by photography that it seems quite familiar when we look upon it in the Royal box or elsewhere. There is certainly less romance, now-a-days, surrounding the persons of princes, princesses, and other great people, than before the days of photography; but if we have lost something in this respect, the balance of advantage is immeasurably in our favour. The disappointment of the lady to whom we have referred would, after all, soon be counterbalanced by the reflection that the photographs of other great personages in her album equally resemble the originals, and thus she may in the future be quite satisfied that she knows what they are like, without taking the trouble to run after them. Indeed our fair neighbour could not have expected to see much more than she did, and if questioned would doubtless have been puzzled to define the something which she anticipated. The stout, good-humoured appearance of the Prince would, if she had reflected a moment, have been equally satisfactory, for the blame, if any blame was to be awarded, should be put upon photography for representing so trustworthily the illustrious personages, without favour or disfavour. It has simply put before our eyes the portraits of a man and woman, and some of us have an idea that princes and princesses are something more than this. Whether the recollections of childhood's stories still linger in our minds, or that we are naturally inclined to romantic fancies, certain it is that many cannot quite get over the notion that princes usually go about in long hose, and pink silk jackets, with feathers in their hats, and ribbons on their shoulders. We used to read about them thus in our early books, and our ideas upon the subject were confirmed by the extravaganzas and pantomimes that we witnessed. Princesses were always beautiful in those days, and it was only the curdmageons of step-mothers who were at all ugly and ill-favoured. Indeed the idea is so firmly rooted, that it is no uncommon thing to hear a person, examining some princess's portrait for the first time, exclaim, "I don't call her pretty at all!" as if, being a princess, she must perforce be good-looking. A contemporary is just now engaged in the issue of a series of portraits called the leaders of society, and we are treated week after week with fair members of the aristocracy, who, however much they may differ from others in dress and pose, have invariably one thing in common—they are all handsome. We are not going to deny that there are fine and charming women among the "upper ten;" all we take exception to is, the universal beauty supposed to exist among the favoured few. Such representations as these sometimes make us wish that photography had never been invented to deceive us. Look at the old engravings of slight damsels with high waists and quaint top-knots that figure in the print-shops around Covent Garden. They are all Countesses, or Lady Sophias, or Honourable Misses, and they are all surpassing fair. No wonder our fathers and grandfathers had wonderful ideas of the charms of high-born ladies. Photography has swept away all this romance, and a lady of the *grande monde* has to take her chance with the rest of her sisters. She is photographed, and, let the portrait be touched or untouched, one gets a

very good idea of her claims to be considered a beauty. Nor is it only in the matter of personal charms that photography has stepped in to tell us a word of truth. In other connexions it is equally frank. The magnificent sights, the lofty waterfalls, the gigantic glaciers, the dangerous passes, and the thousand and one objects about which travellers were wont to tell wonderful stories, and of which sketches would bring us home pictures that would admit of no doubt, have materially decreased in number and importance since the cultivation of the black art. The account of our friend Brown's villa in the country, of his conservatory and flower-buds, of his fishpond and pine-houses, his shrubbery, stabling, and all the rest of it, is all very well; but when, after his glowing description of them, we see a photograph which some itinerant operator has executed for a shilling, we are hardly so much impressed as we were before. There is a garden, certainly, and a cucumber-frame—we mean conservatory—but not of the dimensions we imagined them. Of course it is our imagination that is to blame under the circumstances, and it is a good thing, therefore, if we are prevented from going astray by the aid of a photograph. We have an acquaintance whose whole leisure is taken up with yachting, and when he can spare a moment from stock-broking, he is off to Erith, where his vessel lies, for a cruise. The many times he has invited ourselves to a trip made us some time ago seriously consider about whether we should not join him for a few days' trip. Albeit a bad sailor, we could not resist his accounts of adventures of a run down the Thames to Margate or to Deal, sleeping and eating on board as comfortably as in an hotel. He had an experienced mariner who acted as master, and the latter's qualifications for that post were amply proved by the many cups he had won at races and regattas. If we liked, we should run over to Boulogne or Dieppe, or into some quaint little seaport in Normandy, and look at the pretty French fishwomen in their striped petticoats. Such an invitation as this one could scarcely refuse; but before venturing, we fortunately caught sight of a photograph of the yacht lying off Barking Creek. Adieu romances and sun-lit waves, picturesque Normandy and bonnie fishwives. The picture showed a large row-boat, or something of that sort, rigged, with an untidy sail. There was a cabin, it is true, where one could sleep, but only a part at a time. Head or feet must, perforce, be exposed à la belle étoile, and in a heavy sea you would have to sit with an arm round the main mast to prevent slipping into the sea. Our trip to Boulogne is as far off as ever, and we bless photography to this day for saving us the trip. Therefore, we say, if the camera has robbed something of the romance of this world, we must remember that it has given advantages which more than compensate for the loss, for there are times when we like to get at the bottom of a thing without desiring to go so far as to descend into a well.

A NEW OXYGEN RETORT.

BY WILLIAM J. CHADWICK.*

In bringing before your notice a new oxygen retort I do not claim the credit of any great invention, but simply an improvement in one or two respects upon what we have previously seen.

My improvement consists—Firstly, in making the oxygen mixture in the form of cakes instead of plugs or cylinders, as were first introduced by our friend Mr. M. Noton. Secondly, in the shape of the retort, which is made so that the cake lies upon the bottom, and is only in contact on that side. Thirdly, in making the cakes with the bottom bearing on the retort, to consist simply of manganese, sand, or other substance containing no chlorate of potash, upon the top of which is placed the oxygen mixture, still forming one compact cake. Fourthly, in the perforating of the cakes.

* Read before the Manchester Photographic Society.

image is not more capable of being photographed than the combined colours of which I have just spoken.

An artist engraver produces, in the first place, a relief—either ornament, bust, or head—and of this impressions are prepared in plaster of Paris to which a little red has been added. As many impressions are set up as you desire to have bank-notes on the same printing block, and these impressions are photographed, lighted up sharply from the side. From the negative so taken a Lichtdruck cliché, and in this way a print in blue and red in half-tone, may be secured.

M. Jaffé concludes his paper by stating that if the Lichtdruck process is not far enough advanced at present to produce the perfect prints necessary in the preparation of bank-notes, a combination of photography and mechanical means could be contrived to produce the necessary result.

ON A NEW CAUSE OF PINHOLES AND STREAKS AND ON THE ACTION OF NITRATE OF BARY IN THE NEGATIVE BATH.

BY DR. H. VOGEL.

[WHILST the negative bath and its troubles attract the attention of photographers, it may be attached to the right to reproduce the article by Dr. Vogel, or placed upon a referred in our last, as having appeared.

Years ago in the PHOTOGRAPHIC top portion of the retort an inch it covers much more conveys the gas direct to the gas holder of the Photash bottle, as shown us three meetings ago by Mr. Ponsa for preventing the return of the gas and back pressure, may be used, or an ordinary back pressure valve or an ordinary tap.

The object of using cakes of the above description is that they leave the retort perfectly clean; for, as it is the chlorate of potash that fuses and sticks to the retort, the manganese or sand which forms the bottom of the cake, and is the only portion in direct contact with the retort, is a sure means of preventing any sticking. This plan I also adopted in the case of plugs or cylinders. The perforation of the cakes is simply to facilitate the generation of the gas.

There are other advantages to be derived from the use of this apparatus. As this is more of a social meeting than a scientific one I will not detain you longer, but to anyone interested I shall be glad to show the apparatus at work later on in the evening.

THE BLUE GLASS DECEPTION.

THE *Scientific American* resumes its remarks on this subject. It says:—

"In our last issue we reviewed the alleged capabilities of sunlight filtered through blue glass in causing plants to grow, &c.; and, by reference to numerous experiments, we reached the conclusion that the light transmitted through the violet-blue glass is nothing more than normal sunlight diminished in intensity. We propose in the following to finish our discussion by examining into the effects of light and darkness upon organisms. And we may especially here recall the fact that General Pleasonton claims that not only does the blue light stimulate growth, but that it is a positive remedial agent for such severe ailments as spinal meningitis, nervous irritation and exhaustion, rheumatism, hemorrhage of the lungs, deafness, partial paralysis, shock due to severe contusion, and others, of all of which he cites cases.

"The theory that various coloured lights exercise different effects on the human system is an old one. In 1831 Dr. Newbery asserted that yellow light stimulates the nervous, pink the nutritive, and blue the locomotive temperament; and recently Dr. Ponsa, an Italian physician, has asserted that lunatics are greatly affected by being placed in different coloured rooms. Red light, Dr. Ponsa

Of course such a secretion of crystals of acetate of silver on the collodion film has been repeatedly observed by us and others. These, however, occasion not so much pinholes, as "spears, crosses, and swords," the needle-shaped crystals attaching themselves to the film either singly or with several crossed together, and hindering the action of the light.

Our attention was lately directed once more to this point by a letter from Herr Krüger, of Schwerin. He sent two samples of crystals which had precipitated themselves in his silver bath, and wrote that he had been annoyed the whole summer by pinholes in crowded appeared after two days' use of frames, where the light of when it contained little iodine. The total exclusion of question had secreted an impoverished and disordered one of the blood, emaciation, muscular debility, and the I examined due to imperfect nutrition.

few. On the other hand, it is known that for certain purposes, darkness or shaded light is advantageous to the bodily condition. Fowls, for instance, may be fattened much more rapidly in the dark, and it would seem that the absence of light exercises a very great influence over the power possessed by food in increasing the size of animals. It likewise seems to exercise a soothing and quieting influence, increasing the disposition of animals to take rest, making less food necessary, and causing them to store up more nutriment in the form of fat and muscle. Now, if the organism to be treated is subjected to light all of which is filtered through blue-violet glass, then, as we have previously demonstrated, it is in light which is considerably shaded. And very probably to this cause—and not at all to the peculiar hue of the light—is to be attributed the quieting influence on nervous and insane people which Dr. Ponsa has remarked.

"But General Pleasonton does not use blue-violet glass alone. On the contrary, he employs a combination of blue light and pure sunlight, the latter very much preponderating. In his graperies, for example, only every eighth row of panes is blue. The mingled light consequently is merely pure sunlight, very slightly shaded; and the animal or plant exposed simply takes a sun bath—the solarium of the ancients, who, knowing the vivifying influence of the sunbeams, had terraces built on the tops of their houses, so that they might bask in them. This sun treatment is now frequently recommended by physicians for nervous diseases. Dr. Hammond, in one of his lectures, says: 'In convalescence from almost all diseases, it acts, unless too intense or too long-continued, as a most healthful stimulant, both to the nervous and physical system. . . . The delirium and weakness, by no means seldom met with in convalescents kept in darkness, disappear like magic when the rays of the sun are allowed to enter the chamber.'

"To recapitulate in brief, General Pleasonton's claims of any superior powers for blue glass on account of the colour which it produces in transmitted light are, when tested by the result of previous investigations, unfounded. In some instances, where it is desirable to reduce the intensity of the light, blue glass may be used; but any other mode of shading the light, as by ground glass, thin curtains, &c., would without doubt serve equally as well. The cures produced are ascribable to two causes: first, to the healthy influence of the sun bath, and secondly, to the very powerful influence of the patient's imagination. There are abundant cases known where imagination has so powerfully affected the body as to cause death. "Experiments upon criminals have shown that in one instance, where a person was placed in a bed which, he was informed, had just been vacated by a cholera patient (but which had not), he exhibited all the symptoms of that disease. Another person is reported to have shown all the signs of collapse from loss of blood, from the suppositious idea that he was bleeding to death. As regards the animals fattened under the glass, all the circumstances go to show that the result

sulphate of soda was made, the evaporated water replaced, the whole filtered, and allowed to cool for twelve hours. Small crystals had then secreted themselves on the surface. Several prints made in this bath showed very numerous pinholes. Now this bath was free from iodide of silver, apart from the small quantity which is dissolved in sensitizing; the pinholes accordingly could not proceed from it. It is therefore established beyond all doubt that pinholes are occasioned by sulphate of silver.

However, in the case of this bath, another clear, worm-shaped lines.

A LITTLE while ago I published an incident which I publish my researches upon the Herr Benque colours, which I had undertaken in several prints, view to the production of cheques and other papers, which could not possibly be reproduced by photography. My experiments were simply confined to the ordinary practice of photography, but I conducted them in a particularly searching manner, by reason that information had reached us from the directors of the National Bank of Austria to the effect that the blue bank-notes of France, which hitherto had been considered incapable of being reproduced by photography, had nevertheless been copied by the camera.

I obtained a table of colours which displayed most of the different pigments in a perfectly pure condition in their various phases. This table was particularly suitable to my purpose, for the letters formed by the colours upon a white ground permitted the making of a very uniform comparison, for I had every colour in juxtaposition with white, and could therefore study each effect upon the negative. I made several copies of this table, giving various exposures.

Even the most light-powerful, an impure violet, showed very materially on the white in the photograph, and the cobalt blue behaved in like manner, the latter being the pigment employed in the bank-notes just mentioned. The contrast of the other colours was greater, and they were therefore less interesting from my point of view. From this fact I came upon the process which it is most likely forgers have employed in their work.

It is highly probable that if anyone succeeded in producing a copy from a bank-note printed in cobalt-blue by means of the camera, he had to make use of a very complicated process. He required to have engraved plates, for instance, which he would secure by means of photography. If a blue image printed upon white is capable of giving an image, the latter would nevertheless be much too weak for the direct production of a printing-block. A phenomenon which is generally regarded with dissatisfaction by the photographer is, however, in this particular instance taken advantage of, in all probability, namely, the circumstance that a diapositive of a portrait, or any other picture in half-tone, secured in the camera, is generally harder and flatter than the original negative, and the circumstance also that a negative produced again from this diapositive will lie still more hard and flat.

If we now suppose for a moment that the vigour of the deposit upon our negatives is divided into degrees according to Dr. Vogel's photometer scale, and we put the difference between cobalt blue and white at 2°, then a diapositive produced in the camera will bring this difference easily as far as 4°. The negative from this diapositive will possess 8° of density, and this degree is at once brought to 16° by securing yet another image. As probably 20° of density will suffice for the production of a printing-block, such a deposit is secured with but little difficulty obviously. The exposure must always be shortened with every operation, so that the deposit, which was at first produced by the blue ground, becomes gradually less.

* Photographische Correspondenz.

0.25 per cent. sulphate of silver), was now mixed with $\frac{1}{2}$ per cent. nitrate of baryta, and treated just as above.

The result was the same. I obtained a plate of extraordinary intensity, somewhat hard in the lights, but with many fine details in the shades (of the original), finer than with an ordinary bath. The intensity of the plates made in the second bath surpassed that of those made in the first (which also contained less barium).

I must conclude from these experiments, several times repeated, that nitrate of baryta in the negative bath increases remarkably the intensity of the plates.

It should only be added, however, in a very small proportion to the silver bath, for it belongs to the salts which are difficult of solution in water, and which are precipitated in crystals by alcohol.

If a bath, therefore, contains much barium, the latter is precipitated by the alcohol of the collodion film, and occasions, like all precipitates of that kind, pinholes. With the use of a bath containing much barium, these pinholes could appear to a remarkable extent.

prevent photography, for visible to the negative. But MS FOR PHOTOGRAPHERS.

becomes yellow; become legible, and If silver prints are washed berylation taught me to direct room, numerous little air- which are as inactive as the tint. These remain often theless, appear light to the eye, and stand me, in fact, of covering cheques all of which are inactive colours, the writing and figures being in black ink. I took, therefore, my colour-table in hand once more, and painted upon the yellow, green, and red squares some characters in Indian-ink, and in this condition proceeded to take a photograph of it.

Upon my negative the contrast between the black and cinnabar, orange, metallic-green, and especially light chrome-yellow, was very little. My satisfaction, however, was exceedingly short-lived, for I remembered Dr. Vogel's proposition to employ coralline and aniline green in collodion to render it more sensitive to red and yellow rays. By employing tinted collodion and coloured plates, it was obvious that more marked contrast is to be secured in photographic clichés, and in this way, no doubt, a negative of a cobalt blue cheque could be secured with the proper contrast without recourse to the elaborate process previously suggested. Finally, therefore, I resolved upon employing mixed colours in such a way as to thwart the photographic reproduction.

As I was at the time engaged in lithography and Licht-druck printing, I availed myself of the opportunity to produce results which baffled all results at copying with the camera, and which were secured by printing one layer of colour over another.

I found out a whole series of such combinations, but will only allude to a few of them, namely, cobalt-blue upon light yellow, dark-blue upon green, cinnabar upon chrome-yellow. All these resisted the effects of photography, even with the addition of pigments to the collodion, or the employment of coloured glass plates, because the lower colour is scarcely perceptible to the naked eye, and only shines through the upper one, rendering this rather more actinic.

In this way, therefore, valuable documents may be produced which cannot be photographed. Upon a coloured basis may be printed any type or engraved plate by any of the processes in general use for such work.

But I was enabled to arrive at the goal in another way. I was convinced that while cobalt blue, when in the form of strokes and patches (as it appears on French bank-notes), does not present any insuperable difficulty to the photographer, it is different when the cobalt image is printed in half tone. Printed in lighter and darker tints of blue, the

image is not more capable of being photographed than the combined colours of which I have just spoken.

An artist engraver produces, in the first place, a relief—either ornament, bust, or head—and of this impressions are prepared in plaster of Paris to which a little red has been added. As many impressions are set up as you desire to have bank-notes on the same printing block, and these impressions are photographed, lighted up sharply from the side. From the negative so taken a Lichtdruck cliché, and in this way a print in blue and red in half-tone, may be secured.

M. Jaffé concludes his paper by stating that if the Lichtdruck process is not far enough advanced at present to produce the perfect prints necessary in the preparation of bank-notes, a combination of photography and mechanical means could be contrived to produce the necessary result.

ON A NEW CAUSE OF PINHOLES AND STREAKS, AND ON THE ACTION OF NITRATE OF BARYTA IN THE NEGATIVE BATH.

BY DR. H. VOGEL.

[WHILST the negative bath and its troubles are under the attention of photographers, it may not be inappropriate to reproduce the article by Dr. Vogel to which we referred in our last, as having appeared upwards of eleven months ago in the PHOTOGRAPHIC NEWS. It is curious how thoroughly it covers much of the ground traversed at the last meeting of the Photographic Society.—ED.]

Among the many defects in the negative process, none is so frequent as pinholes in the collodion film. Every photographer is familiar with these troublesome spots, which are most prone to make their appearance in the case of old silver baths, and the chief cause of which, apart from dust, is the iodide of silver dissolved in the bath, which finally (when the bath is saturated with it) tends to crystallize in combination with nitrate of silver, adheres to the collodion film whilst in the bath and during the development, and finally leaves behind a small hole, at first scarcely visible, but coming out more clearly by contrast when the print is strengthened.

Two years ago we devoted special attention to these precipitates of iodide of silver, and made several remarkable observations, which threw light upon the action, hitherto in so many particulars obscure, of old silver baths.

We showed at that time that iodide of silver is less easily soluble in heat than in cold, and that, therefore, on hot days silver baths soon become turbid, and grow clear again by simple cooling. We also showed that iodide of silver is more easily soluble in acid and alcoholic baths than in those containing only pure water and the silver salt.

Hence was easily explained the formation of pinholes in the heat of summer, or after the neutralizing of the bath; and our friend Mr. Wharton Simpson showed the correctness of our results in a series of comparative experiments.

Singular phenomena still, however, presented themselves, which could not be harmonized with this theory of the formation of pinholes.

Herr Kurths, of Magdeburg, wrote to us, that at a low temperature (4°) he had found pinholes, which on warming the bath to 12° disappeared. A similar announcement was made to us by Dr. Lorent, of Maimheim.

The combination of iodide and nitrate of silver could not be the sole cause of these phenomena, for at a low temperature it not only does not precipitate itself, but even dissolves, as may easily be observed on the cooling of a bath that has become turbid in the heat.

We sought the further cause of the defect in other salts scarcely soluble, which dissolve less readily in cold than in heat, and must therefore precipitate themselves on cooling; the acetate of silver, for example, which originates so easily in the bath through the adding of acetic acid, or through the decomposition of the alcohol contained in it.

Of course such a secretion of crystals of acetate of silver on the collodion film has been repeatedly observed by us and others. These, however, occasion not so much pinholes, as "spears, crosses, and swords," the needle-shaped crystals attaching themselves to the film either singly or with several crossed together, and hindering the action of the light.

Our attention was lately directed once more to this point by a letter from Herr Krüger, of Schwerin. He sent two samples of crystals which had precipitated themselves in his silver bath, and wrote that he had been annoyed the whole summer by pinholes, which often appeared after two days' use of a new silver bath, even when it contained little iodide of silver. The crystals in question had attached themselves on the evaporation of one of the baths.

I examined the crystals, and found, besides iron and a splinters of glass, a considerable quantity of sulphate of silver.* This result surprised me, as I did not at once suspect the source of this impurity. A second letter from Herr Krüger gave the necessary explanation, informing me that in the examination of the spoiled baths he had likewise discovered sulphuric acid, and that this arose from the impure iodizers which he had applied. At the same time he sent me the iodizers mentioned, and the impure bath, and there I found indeed sulphuric acid along with carbonic acid (in the iodizer).

The source of the sulphuric acid in the bath was now discovered. A part had got in the bath at first by iodizing it with a little iodide of potassium. Every new collodion plate had increased the quantity of it, and the most probable supposition was, that the salt, with its known difficulty of solution, had rapidly precipitated itself, and occasioned the pinholes.

In order to test whether the sulphate of silver really occasioned pinholes, I made a silver bath 1:10, and mixed this with $\frac{1}{4}$ per cent. of iodide of potassium, and tested it. There were no pinholes.

To 200 cubic centimetres of the bath were now added 0.8 grains of sulphate of soda. A considerable precipitate of sulphate of silver was formed. This was filtered, and in the filtered bath a plate was made. On sensitizing, it appeared covered with small crystals, and after being exposed to the light and developed, it swarmed with little pinholes.

Here, however, a considerable quantity of silver (about 4 per cent.) had been precipitated as sulphate, and there was reason to suspect that thereby the power of solution for iodide of silver might have been lessened, and thus the pinholes caused. I therefore repeated the experiment, taking 200 cubic centimetres of a new freshly iodized bath, and shaking it with fixed sulphate of silver. Here the quantity of nitrate of silver remained the same.

Only very little sulphate of silver was dissolved, and I obtained a bath which contained of sulphuric acid much less than that of Krüger, and also gave but few pinholes. During the night, however, the bath cooled considerably, and next morning it gave numerous pinholes.

The cause, however might still be laid on the iodide of silver which was present. I therefore made a third bath without iodide of silver—

Water	200 cub. cents.
Nitrate of silver	2C grains
Sulphate of soda	0.5 grain

A precipitate of sulphate of silver was thereby formed. The whole was now heated to 90° C. Notwithstanding this, the precipitate dissolved with extreme slowness, and even after an hour-and-a-half there was still a small residuum—a proof that 100 cubic cent. of a silver bath, 1:10 at 90° C., is hardly capable of dissolving $\frac{1}{4}$ grain of sulphate of silver. A further addition of 0.5 grain of

* Mr. Mayall recently mentioned to us that, as the result of the examination of an old and imperfect bath, sulphate of silver was found in it.—ED.

sulphate of soda was made, the evaporated water replaced, the whole filtered, and allowed to cool for twelve hours. Small crystals had then secreted themselves on the surface. Several prints made in this bath showed very numerous pinholes. Now this bath was free from iodide of silver, apart from the small quantity which is dissolved in sensitizing; the pinholes accordingly could not proceed from it. It is therefore established beyond all doubt that pinholes are occasioned by sulphate of silver.

I observed, moreover, in the case of this bath, another remarkable phenomenon, viz., clear, worm-shaped lines. These lines remind me strongly of an incident which occurred in the Photographic Association. Herr Benque exhibited at the session of the 17th of March several prints, upon which quite similar lines were visible. Nobody was able at that time to give a satisfactory explanation of the phenomenon: Herr Schippang and Herr Prumm ascribed it to the iodizers.

I believe that I can now, with tolerable certainty, assign as the cause of these strange phenomena the presence of sulphate of silver, and it may be that this has been produced by the impure iodizers. The matter induced me to examine several of the commercial samples of iodizers, and I readily found in these sulphuric acid and carbonic acid.

There are, besides, other sources of sulphuric acid in photographic baths. It may proceed (2) from impure nitric acid, which was employed in the dissolving of the silver (as Herr Krüger has already asserted); (3) from acid pyroxyline; and (4) from impure blotting paper. The latter not seldom contains sulphate of lime, and also sulphate of soda, as a residuum from the bleaching process with antichlor.

It is obvious, therefore, that the presence of sulphuric acid in photographic chemicals is much more frequent than one would suppose, and it appears to me highly probable that the formation of pinholes in cold weather (as observed by Herr Kurths and Dr. Lorent) proceeds from it.

These experiences may induce manufacturers to direct their attention to this, hitherto entirely overlooked, the presence of sulphuric acid in photographic chemicals; and we advise photographers to test their chemicals themselves for it.

This is best done with the aid of nitrate of baryta, which is to be added to a solution of the substance to be tested, acidified with a few drops of nitric acid. The presence of sulphuric acid betrays itself by producing a turbidity. To test, in this way, silver baths containing iodide of silver in order to detect sulphuric acid, requires caution, since iodide of silver precipitates itself, and likewise occasions turbidity; two or three drops of nitric acid should be added to four cubic cents. of bath solution, in order to prevent the precipitation of iodide of silver, and not till then a few drops (as few as possible) of nitrate of baryta solution. The turbidity does not show itself for some time. It is better, however, to precipitate the silver with pure hydrochloric acid, to filter, and then to test for sulphuric acid.

Now I tried, by mixing with nitrate of baryta, to precipitate the sulphuric acid in the negative baths which contained the latter, and which produced pinholes. In connection with this, I made a remarkable observation.

I added 0.8 solid nitrate of baryta to the first bath (200 cub. cents.), shook it, and let it stand till the next day; then filtered off the sulphate of baryta which had been produced, and made a print in the bath. This showed now no pinholes, but an *astonishing intensity* immediately after development, so that it could be printed immediately without any strengthening. The plate appeared only a little hard.

The bath contained, as I establish by examination, a little barium.

The second bath, containing sulphuric acid* (it contained

0.25 per cent. sulphate of silver), was now mixed with $\frac{1}{2}$ per cent. nitrate of baryta, and treated just as above.

The result was the same. I obtained a plate of *extraordinary intensity*, somewhat hard in the lights, but with many fine details in the shades (of the original), finer than with an ordinary bath. The intensity of the plates made in the second bath surpassed that of those made in the first (which also contained less barium).

I must conclude from these experiments, several times repeated, that nitrate of baryta in the negative bath increases remarkably the intensity of the plates.

It should only be added, however, in a very small proportion to the silver bath, for it belongs to the salts which are difficult of solution in water, and which are precipitated in crystals by alcohol.

If a bath, therefore, contains much barium, the latter is precipitated by the alcohol of the collodion film, and occasions, like all precipitates of that kind, *pinholes*. With longer use of a bath containing much barium, these pinholes would appear to a remarkable extent.

APHORISMS FOR PHOTOGRAPHERS.

BY FRITZ HAUGK.*

1. *Caution in Washing Prints.*—If silver prints are washed in very cold water in a warm room, numerous little air-bubbles affix themselves to the print. These remain often very obstinately upon the photographs, and stand in the way of the picture being freed from hyposulphite of soda. It is advantageous, therefore, to wash prints in boiled water that has cooled, or to keep the prints so much in motion that the air-bubbles are destroyed.

2. *Stoppers for Varnish Bottles.*—Varnish bottles are best closed with stoppers formed of good and pure wax, or corks may be used which have previously been dipped in molten wax. If corks are employed with no wax coating, they very often stick fast in the bottles, and particles are often removed which render the varnish impure.

3. *The Production of Special Bust Pictures.*—The vignette masks have nearly all of them a pear-shaped outline, and in printing, the broad part of the opening is laid upon the breast of the portrait. In this way the picture is printed. A more beautiful effect is secured, however, when the vignette mask, after the print is about three-quarters finished, is turned round, and the broad part of the opening is put uppermost. In the case of ladies with very large head-dresses this method of printing has especial advantages.

4. *Retouching Powder.*—This powder is prepared by mixing together—

Dextrine	2 parts
Resin, very finely powdered	1 part.

It may be employed both for application to negatives and to albumenized prints. A leather stump is the best means of application.

5. *Net-like Cracking of the Film.*—In employing a collodion prepared with alcohol of too weak a nature, the film is apt to tear, as soon as it becomes dry, in a net-like form. If these cracks occur only in places, the collodion may readily be freed from the defect. It is only necessary to add to it an equal quantity of another collodion, in the preparation of which absolute alcohol has been employed. Another way, also, of helping oneself is by collodionizing the plate more quickly, and not permitting it to dry so perfectly. In the case of strongly iodized collodion, another error may, however, arise, which is known by the name of iodine streaks or flames. But this fault, unless it is very rampant, is only to be seen on the top of the image. In this case the plate should be turned round on the dipper before being put into the dark slide, and redipped, the plate being raised and lowered half a dozen times.

DRYING CARBON TISSUE.

ONE of the practical obstacles to success which trouble many carbon workers is the difficulty of drying the tissue after sensitizing. The greediness of gelatine for water readily explains its slow drying tendency, and the readiness with which gelatine saturated with water melts on the application of heat explains the danger of applying a high temperature to get rid of the water. No aid to drying the sensitized tissue has been found so efficient as a current of warm dry air. But as the tissue must be kept in the dark, this mode of drying is not always easy of application. Very slow drying, besides being inconvenient and obstructive of the despatch of business, has been found to promote spontaneous insolubility in the tissue. Very rapid drying has been said to cause reticulation in the texture of the prints; but this, as we shall show, is not a necessary or universal concomitant of quick drying, even when effected by the aid of heat; whilst the use of alcohol, and such aids to desiccation, have been found preventive of reticulation.

A mode of applying heat for quickly drying the tissue has recently been brought under our attention by Mr. Mayland, who finds it possible to have the tissue exposed under the negative in the pressure frame within an hour of commencing to sensitize the tissue. It is dried in a drying box a few feet square, at the bottom of which is a sheet of tin, immediately under which is an Argand gas burner. On the tin is a shelf of wood. The sheets of tissue, after sensitizing, are treated with the squeegee to remove all surface water, and then hung up in this drying box. A sliding door, sliding upwards to open, is left open at the bottom about an inch, and through the narrow aperture thus left open the air enters freely, causing a current in the box. This is aided by the fact that the sliding door fits loosely in its grooves, and at the top, leaving space for the exit of the heated air. The result is that the tissue dries in about thirty minutes, and Mr. Mayland has not found the gelatine to melt or run in any instance. The temperature of the atmosphere of the box whilst drying the tissue is from 100° to 130° Fahrenheit. During the late discussion on carbon printing at the Photographic Society, Mr. Sawyer mentioned very rapid drying as having been found at the Autotype works a specific means of securing reticulation. Mr. Mayland's drying process is much more rapid than that mentioned by Mr. Sawyer, and he (Mr. Mayland) has never in a single instance found a trace of reticulation. It is probable that in the instances observed at the Autotype Works some other agency had been at work concomitant with the quick drying, and to such agency the reticulation had been due.

The method described in our pages a few weeks ago, by Mr. Charles Waldack, as employed by M. Gernez, a

highly experienced carbon printer, for securing quick drying, seems to be very promising. After removing from the sensitive tissue excess of solution by means of the squeegee, he places the tissue in alcohol. As many of our readers know, alcohol is even more greedy of water than gelatine is, and during a short immersion the water is withdrawn from the tissue by the alcohol, and the issue is that after this treatment, and hanging for about half-an-hour, the tissue is ready for the pressure frame. The alcohol may be used for a few times, but of course, as it absorbs water each time, it gradually loses its efficiency, and will require re-distillation. As methylated alcohol will serve every purpose, this need not be found a very expensive expedient, as it will be specially beneficial in hot weather.

It has been proposed to use alcohol in the sensitizing bath as a ready means of meeting the trouble in drying. But the fact that bichromate of potash is entirely insoluble in alcohol places a serious difficulty in the way. M. Vidal has found, however, that the addition of a portion of alcohol is possible with good effect, and M. Boivin states that a sensitizing bath made as follows answers perfectly, and that the tissue dries readily—

Water	70 cub. cents.
Alcohol	30 "
Bichromate of ammonia	3 grammes
Ammonia, from	1 to 3 drops

This would give a bath containing three ounces of alcohol for seven ounces of water, and about eighteen grains of bichromate of ammonia and a drop or two of liquid ammonia for each ounce of water.

So far we have been dealing with what has been actually done, and, as is alleged, with beneficial effect. But this is a very promising and fascinating direction for experiment, and it may be well to indicate some possibilities for the aid of experimental readers, and also for practical carbon workers, to whom this drying question is one of vital importance.

It is to be remembered, at the outset of experiments in this direction, as was ascertained in the early experiments of Mr. Swan and others, that chromic acid is the actual sensitizing agent, although it has been found convenient in practical operations to use an alkaline chromate. Whilst these chromates are, however, insoluble in alcohol, chromic acid itself is soluble in alcohol, and also in ether. It is probable that an alcoholic solution of chromic acid might be found available for sensitizing the tissue, when all difficulty in drying would be at an end. Or, probably, better still, would be found the tetrachromate of potash, which is soluble both in alcohol and in water, or in a mixture of the two, and this would, we have no doubt, be found in every way available for sensitizing the carbon tissue, without any risk of solution or running of the gelatine in warm weather, and present no difficulty in securing rapid drying. The chief practical difficulty to be anticipated in applying either of these preparations would consist in the fact that an alcoholic solution of chromic acid, or of tetrachromate of potash, is readily liable to spontaneous decomposition if submitted to the action of light, or to a high temperature; but no serious difficulty need exist in avoiding these conditions of failure. We commend the experiment to the many ingenious carbon workers whom the question concerns, and shall be glad to learn the results of experiment.

A NEW METHOD OF ARTIFICIAL LIGHTING FOR PORTRAITURE.

MR. VANDERWEYDE has called our attention to a distinctly new and very bold attempt to apply artificial light to the purposes of portraiture, which promises a large amount of success. From the earliest days of photography the possibility of applying artificial light to purposes of portraiture has been the subject of much speculation and

experiment. Many attempts have been made with various forms of light and appliance. Pyrotechnic compounds of various kinds, yielding a light rich in photogenic rays, have been tried, and, so far as the mere obtaining of a light sufficiently actinic to impress a photographic sensitive surface goes, not without success. The lime light, the magnesium, and the electric lights have all been tried, each with a measure of success. The primary difficulty has been in applying any of these lights so as to secure satisfactory illumination of the model, and to obtain artistic light and shade in the resulting picture. The conditions of an artificial light consisting of a point or concentrated source, are opposed to the conditions of ordinary portraiture, in which parallel solar rays are, of course, always used. In a picture it is necessary to a satisfactory and natural presentment that the objects should be lighted as they are usually seen in nature, and this is not secured where an intense concentrated light is the source of illumination. And the usual results produced by the use of such lights has been at once unnatural and unpicturesque. The lights have been harsh, chalky, and without gradation or detail, and the shadows black, dull, and without the transparency due to reflected lights by which the deepest shadows are relieved in ordinary daylight illumination. Reflectors of various kinds have been used to overcome these difficulties, and at times with some degree of beneficial effect, but not with sufficient advantage to bring them into practical operation.

It is obvious that in a country where not only are so many of the hours devoted to active life, sunlight is absent; but also where during the hours of daylight, so many of them are characterized by fog and other atmospheric conditions rendering photographic operations next to impossible, that any method rendering the portraitist independent of either bright sunlight or ordinary daylight, must be regarded as a great boon worthy of all consideration and acceptance. And any method which promises in a practical way to effect this must be hailed with a glad welcome by all photographers. Hence we feel especial interest in bringing the new method under the attention of our readers.

From the commencement of Mr. Vanderweyde's connection with photography as an artist he has felt that the lighting of the model was the operation of primary importance in securing successful results, and he has devoted much study to the various methods employed. The mode of lighting the studio with which his name is associated was one outcome of this study, and the present method of applying artificial light to illuminating the model is another result. After trying various artificial lights he has satisfied himself that there is none so actinic and so constant as the electric light, but, being emitted from a point, none more inapplicable to the purposes of portraiture. But it is to obviate the difficulties dependant upon the concentrated character of the light that the new system is devised. The light having been prepared by one of the various methods available—we may mention, in passing, that Mr. Vanderweyde is using a Gramme machine, gaining his power by a gas engine—a concave reflector is placed at a suitable distance behind it. At a suitable distance in front of this is placed a large lens of forty inches diameter. The lens used by Mr. Vanderweyde is one of Fresnel's dioptric lenses used in lighthouse illumination.

By this lens the rays from the concave reflector are collected and brought into a cone—not, indeed, coming to a sharp focus, as they would be by a lens of perfect optical qualities. At the focus of this lens, at which a disk rather than a point of light is produced, the sitter is placed, where he is bathed in an intense, but still soft flood of light, having the appearance and quality of concentrated daylight, or the direct light emitted from a very bright white cloud, which, as photographers know, is one of the most pleasant and efficient sources of illumination. The time of sitting, as will be understood, may be controlled by

the intensity of the light employed. In the excellent examples of portraiture produced in Mr. Vanderweyde's experimental operations the sittings generally averaged thirty seconds or under.

As we said at the outset, the project of applying artificial light in this manner is as bold as it is original, and, judging by results, we may fairly add, as successful as either. We need not dwell on the multiplicity of applications possible, as they will readily occur to the minds of photographers. We are unable at present to state in what manner the project will be made available to photographers. The method is patented, and a Company, entitled the Photogenic Company, Limited, is formed to work it. We shall keep our readers duly informed of further progress.

PHOTOGRAPHIC EXHIBITION IN AMSTERDAM.
We recently announced details of the forthcoming Photographic Exhibition in Amsterdam, and gave a list of the medals offered for excellence of various kinds. We are now authorized to announce a further medal. The Photographic Society at Amsterdam has resolved to give a silver medal for the best photographic ceramics, and photographs on stained glass. We hope that many competitors in this country will send contributions to this International Exhibition, which is undertaken with so much spirit and liberality by our photographic friends in Holland.

THE PHYSIOLOGICAL ACTION OF LIGHT.

Some curious experiments undertaken by Professor James Dewar, M.A., although appertaining more to the province of the physiologist than to photography, deserve to be mentioned, on account of their contribution to the science of light. Mr. Dewar has for some time past been engaged in noting the influence of light upon the eye and animal system, and has employed the electric current to register the variations set up by light of different intensity.

It may be mentioned, in parenthesis, that Mr. Dewar's experiments were conducted with animals in a state of stupor, except in one particular instance, when he operated upon a human animal—presumably himself. A current of electricity was made to pass along a wire and through a galvanometer to register its intensity, and then one pole was placed in contact with the cornea of the eye, and another either in contact with the brain or the cranium. Light was then permitted to shine upon the eye, and as the amount of light was increased, or lessened, a corresponding change in the electric current was observed upon the galvanometer needle.

The variation, it seems, is the same in warm as in cold-blooded animals. Light causes a *positive* variation of the needle, it is found, and an increase in the electric current. As soon as light is admitted to the eye, the movement of the needle is very marked; "in the case of the lobster," says Mr. Dewar, "the variation caused by the impact is greater than what we have noticed in any other animal, often amounting to one-tenth of the total amount of current." Another point worthy of record is that "light falling on the one eye causes the needle to move, say to the left, while, if it fall on the other eye, the needle swerves to the right."

These experiments of Mr. Dewar's prove how intimately light and electricity are connected with one another.

TRANSATLANTIC WRINKLES.

BY LAFAYETTE HARRISON.

No. II.

SOME few months ago an editor of a New York daily perpetrated a disgraceful newspaper joke. He caused an alarming account to be published of a mythical escape of

the wild animals in Central Park, stating that they were still at large, and detailing frightful scenes of carnage in a most vivid and natural manner. It was a bright afternoon, and hundreds of children had been sent to play in the park. The effect of the announcement was terrific—the whole city was panic-stricken. No one read the article through, but just rushed off to the supposed scene of blood. Had they done so they would have seen at the end that "The moral is, it is a huge hoax."

The readers of this journal must have themselves appended a similar moral to my last paper in the *News* (p. 115), where, in clean out type, they were frantically besought to flow their negative plates with a solution of water and the yolk of an egg. Probably not a few added, "That tarnation American is getting at us."

I assure you that I never laughed more heartily in my life than when I read the error. I felt that it was too absurd to mislead any professional artist, but I could not help picturing the tyro, fancying that as Howe discovered the eye of the needle to have been in the wrong end, so he had been using the wrong part of the egg, and, struck with the brilliancy of the idea, I could see him soberly coating a plate with a diluted chicken-in-embryo, and I must admit that I laughed until the tears came. Probably it is the best photographic joke ever made. The dream of my life is realized—I shall be immortalized.

If, however, it has really misled any one, I shall regret it. At the same time, I warn each enraged amateur that I have had the ("chronic") sentence "Back in an hour" painted on my office door, that my landlady is provided with a Colt's revolver, and that there is a dog in a perennial state of hideous madness on the premises, so that I wouldn't advise him to seek redress. Sub-rosa: At the urgent request of anxious friends, I quit, this night, for Yokohama. My witty countryman, Max Adeler, tells of a compositor whom he styles "intelligent," who, for the poetic line,—

"He watched the window till all hope had vanished,"

substituted,

"He washed the window sill with soap and varnish."

As if matters were not bad enough already, the compositor represented me as saying—"nitric acid and water, in which place overnight the prints," instead of *plates*. Altogether the joke may be termed unique. Need I say that in both cases where the word *yolk* is used, read *white*? Send the yolks to the kitchen, unless you keep cyanide of potassium lying around loose. In the latter case throw it over your neighbour's wall—if he keeps a cat which annoys you. As Toole would say, "Give the animal a treat." With this amendment, try albumenizing. Your films will never crack or peel.

A word to you plate-polishers. If you notice a film beginning to peel, flow it with ale. If it is still more serious, and, besides peeling, requires more intensifying, use porter, which will serve the two-fold purpose of saving the film and adding density.

At the end of the summer every photographer who does any business regards with melancholy a big heap of rejected varnished negatives. If he attempts to clean them, he knows by experience the labour required, and the dustmen refuse to have them at a gift. What is he to do, therefore? To which conundrum I answer:—Procure at the oilman's one pound potash-ball (otherwise called concentrated lye); break it into small pieces, and dissolve it in four gallons of hot water. Place the discarded negatives therein, and in about half an hour, more or less, according to the hardness of the varnish, the film will easily scrub off. This amount of lye water will clean almost any number of plates. Next put the glass in your nitric acid solution, or, better still, in Lea's bichromate solution, the formulae of which I will subjoin for the benefit of those who are ignorant of it:—

Bichromate of potash	2 ounces
Sulphuric acid	2 ounces (fluid)
Water	25 "

(N.B.—This bath is good as long as it is of a yellowish brown colour; when purple it ceases to act).

Let the glass soak in this for a couple of days, and then albumenize as with new glass, and you will get good results. No stains or ghost of the former image. As the lye solution is pretty strong, it may be a Samaritan act to warn you not to dip your fingers therein, unless you wish, like the Ethiopian, to "change your skin."

To remove unvarnished films which have dried, dip a damp sponge or flannel rag into some coarse salt, and rub the film off with this; the most stubborn will quickly disappear. Then soak the plate as usual in the nitric acid, or whatever glass cleaning solution you use.

There is, undoubtedly, a degree of finish in American photographic productions seldom if ever to be seen in those of this country. It will be my endeavour in a future paper to point out wherein the differences lie, and attempt to give a few "wrinkles" which shall enable any true artist, anywhere, to turn out equally effective work; but at this present I shall merely touch upon that which is most apparent, viz., the burnish or glossy surface.

Burnishers seem to be out of favour in this country. Photographers who possess them do not use them (or at least this is the case with very many), and those who would otherwise be purchasers hold back because of the evil reports of the "goings on" of the said machines. The reports, so far as I have been able to learn, are that it both blisters and scratches the prints, therefore it is put aside to rust, or sold at a bargain to the first buyer. If anyone were to show these burnisher-possessors how this might easily be overcome, I take it that he would be performing a good service. I venture so to do, but do not expect to get thanked for it, because of its simplicity. I owned as a boy one of those paper-cover, dime books on "Magic," in which a story was told of a gentleman at an inn being considerably mystified by a countryman who caused a silver half-dollar to vanish. Again and again the trick was performed, and the gentleman felt himself so baffled that he said (I quote the book from memory), "This is most wonderful, and can only be accomplished by the most complicated of means." Then, calling the man, he said, "Show me how the trick is done, and this five-dollar bill shall be yours." The man complied. It all proved to be simple sleight-of-hand. At which discovery I remember the gentleman was highly indignant. Moral:—He wanted more for his money.

Nevertheless, you shall learn how to set your burnishers going, and keep them in order. If they scratch now, polish the nickel plate with a jeweller's hone (price one shilling). Take a sheet of unglazed note-paper folded, as usual, in half. Turn down the top about half-an-inch; turn this fold down twice more (as if you were making a paper spill, the short instead of the long way of the sheet). Then fold the paper in half, so that what was at first the bottom of the sheet comes flush with the rolled or folded part. This, you will see, makes a kind of wedge. Pass this through the burnisher a number of times before commencing, and once before burnishing each card. The object attained is this—it passes smoothly through the burnisher until the thicker or rolled part of the paper, which gives it a brisk wipe the whole length, removes all grit and dust, and the cards come out clean, and with a bright polish.

If the cards do not slip well, make a lubricator of two grains of Castile soap, scraped very fine, and dissolved in six ounces of alcohol. Apply this lightly to the face of each card—shortly before beginning to burnish—with a tuft of cotton wool.

Don't use too much pressure in burnishing—half that of rolling; and so long as you do not over-heat the plate, your prints will never blister.

CARBON PRINTING.

BY A. WELLESLEY TURNER.*

Development.—The flat zinc dish being previously filled with water at a temperature of about 80° or 90° Fahr., the first plate of prints squeezed is placed therein, and left till the gelatine is seen dissolving round the edges; the tissue is then carefully stripped from the plate, which is next placed in the vertical dish, also filled with water of a similar temperature to the first; each plate is treated in this manner, and by the time the operation is completed we shall find that upon drawing the first one out of the dish, it will probably be nearly developed—that is, most of the soluble gelatine will have run off the plate, and left the image visible; the flat dish is again filled with fresh warm water of a higher temperature, if thought necessary, and the prints are thoroughly washed till they appear in all their beauty and perfect sharpness. By this means the development goes on to a great extent without any trouble, and supposing the prints have been properly exposed, as each plate is taken out in succession it will be found nearly finished; should they, however, be a little dark, they must be treated to much warmer water in the flat dish, or, what is more convenient, they can be left for longer immersion in the vertical dish. There is one great advantage in this method of development—we can see very readily how the prints have been exposed. If they are under-printed, we have the consolation that we could not have saved them by other treatment, as they are first developed at a low temperature as practically possible; but should they, on the other hand, be over-printed, we have only to return them to the warm water, and let them soak till they have come down to the proper depth. I have found they will do so much more by leaving them a long time in a vertical dish of water about 100° than by raising the temperature much higher and washing in a flat dish. All the prints properly exposed I wash in warm water, and finish immediately, but return the others to the vertical grooved dish. If only slightly over-printed, half-an-hour's immersion may be sufficient to bring them down, but in some cases they may be left for hours. It is surprising the control we have over the printing by this means. I have had, on one or two occasions, several plates of prints that were hopelessly over-printed if treated by any other method but by leaving them all night immersed in water that in the first instance was not much over 100°. I have by the next morning found them brought down to the proper depth. I would not, however, advise too great a reliance being placed on this in printing, but I would strongly impress the importance of proper exposure. I merely mention it to show the great control we have over the printing in the development, and to prove that the process is not of that exacting character some imagine, as well as the fact that it will be found useful in many cases to the practical worker.

When properly developed, they must be well washed in clean cold water; this finally washes off any remaining dirt, and sets the gelatine, which is afterward further hardened by pouring a solution of alum over them and leaving it on a few minutes, or by putting each plate of prints in a flat dish, for a short time, filled with the same. It is important that this branch should not be done carelessly, as on it depends, to a great extent, the durability of the high gloss if they are required so. When thoroughly hardened with alum, the prints are less liable to absorb moisture from the atmosphere, and thereby lose the beauty of their surface to a great degree.

Each plate of prints is next returned to the rack and dried spontaneously, or, if required, can be dried with a gentle artificial heat; but I prefer the former method. When dry, the prints are spotted in the same manner as enamelled silver prints. There are many ways of doing this, all, I am afraid, open to some objection. I

always use oil colours applied with a small sable pencil. Sometimes the carbon tissue dissolves in warm water is used; but as this is not essentially part of the printing, I will, on this occasion, now pass on to the

Application of the Transfer Paper.—With this branch the beginner can hardly fail; the plan of doing it is so obvious and simple that I need not occupy much space in describing it. The transfer paper is cut about a quarter-inch smaller than the plate all round, and placed in warm water of about 70 or 80° Fahr., where it is left till thoroughly soft, and the surface feels slimy when touched with the fingers. Some samples require much longer soaking than others, and I have had some that refused to get properly soft with almost any amount of soaking. This description of paper is liable to show light brilliant spots on the prints when transferred, in consequence of its not properly adhering to the film composing the image in those parts; such paper, I need hardly say, is not good, but it may be reserved by large work. The transfer paper, when in condition, is carefully raised from the warm water by the two opposite corners, and lowered upon the plate of prints previously placed on the flat board, and gently but well squeezed.

Mounting, at which stage we have at last arrived, cannot be commenced till the transfer paper is somewhat surface-dry, or entirely so, that is if the prints are required with high gloss, of which class I will first speak. They are then marked at the two top corners and each side with blacklead pencil by holding them up and seeing the position of the print by transmitted light; but this can only be done when they have been tinted to the extreme edge, forming, as it does, a guide for placing the mount, which is then damped on one side with a sponge; the transfer paper in that part covering each print is covered with strong size or Russian glue and sugar; the damped mount is adjusted in position by placing it exactly up to the top marks, and bringing it carefully down the side ones; do not, if possible, raise the mount after it has once been laid down, as by doing so the mounts often refuse to afterwards stay flat or properly adhere to the transfer paper. They are next put under slight pressure to allow the size to set, and I then stood up in a warm room to dry. Twelve hours should be allowed for this purpose, for if stripped sooner the dampness from the transfer paper or size may still be retained, and will work its way through, ultimately destroying the high gloss of the surface, although it may not appear immediately. *Never hurry the drying* in this branch, as they are always better when dried slowly than quickly; the less rapid the drying the flatter the print will be, and finer the surface.

When dry strip from the plate, and trim. For mounting with high gloss, without the tinted edge, it is only necessary, when the transfer paper is sufficiently dry, to place over the whole with size or strong paste a very thin sheet of card, or one or two thicknesses of transfer paper; dry, and strip from the plate; trim them in a similar manner to ordinary silver prints; next apply with a small brush, round the four edges of the card, a strong solution of Russian glue or other similar body, and place them in position on the mount; cause perfect adhesion by gentle pressure; the thin card in this instance is only used to keep the prints flat, and to prevent moisture of the glue from destroying the surface.

Another very good plan of mounting is to strip the prints from the plate when the transfer paper is dry, trim with the ordinary card or cabinet outer, damp and mount in the same way as you would a silver print; by this means we lose the high gloss, and obtain one less brilliant, but it is easier done, and some prefer the appearance of the resulting picture; for this purpose we can use a tinted, plain white, or no border at all, according to taste or convenience.

In concluding my remarks upon this subject, which I trust may be of service to some, at least, of my readers, I have only to add, that I have given without reserve what-

* Continued from page 134.

over I have thought may be useful to the profession. Others, in working the process, may find a lack of information on some points, and I would advise all who can to see the operations for themselves; this will teach far more than all I can write, for we often omit in written instructions what is very important to the successful working of a process, merely from the fact that familiarity with certain operations makes us think so little of them that when we sit down to write they slip our memory. I can only say that however much I may have omitted, I have not stated anything but what I know will practically aid in making it a successful operation. I do not claim any part of what I have written as essentially new; I have only put together most of what has been previously published in this journal, and so formed a chain of it with my own experience, in hopes of bringing the process more prominently before my readers, and rendering it useful to them.

Correspondence

MR. FOX TALBOT AND BICHROMATE PROCESSES.

DEAR SIR,—Three years ago, when lecturing at the Royal Institution, I intended to make use of a letter I had received a day or two before from Mr. Fox Talbot, but I had only time to refer to it in the very slightest way. I had, however, in my lecture last week an opportunity to read two or three passages from it, and I was struck with their historical interest, an interest which I believe to be sufficiently great to justify me sending you the following copy:—

“4, Circus, Bath, Feb. 15th, 1874

“Dear Sir,—I will send you to-morrow three specimens of my engraving. This art was discovered in 1852, and published in 1853. The great difficulty at first was to obtain the semi-tints. It was found easy to copy letter-press engravings, or anything merely black and white; but graduated shading offered a difficulty.

“The main fact upon which the art reposes is the photographic quality of bichromate of potash when mixed with gelatine, discovered by me in 1852, concerning which, as it was a great step in photography, allow me to say a few words.

“Mr. Ponton discovered in 1839 that paper became sensitive to light when washed with a solution of this bichromate. No use was made of this knowledge for thirteen years, when, in 1852, I attempted to engrave, and after various other things had been tried, with results more curious than useful, I thought of trying the bichromate mixed with gelatine, which proved successful. I had rather anticipated a failure, because many other photographic substances will not unite with gelatine, but cause it to curdle. I have always considered this process to be one of the most useful things I have done in photography. I sent a great many specimens to Monsieur Biot, which were given away by him at a meeting of the French Academy of Sciences in April 1853. Several writers on photography have fallen into error, and attributed the discovery to a Frenchman, who published it anew, I believe, two or three years later.—Believe me, yours very truly,
H. FOX TALBOT.”

It is certainly interesting that Mr. Fox Talbot, who holds the rank of pioneer of the photographic processes in this country, should have discovered the process upon which is based nearly the whole of the present methods of permanent printing.—I am, dear sir, yours very truly,
43, Piccadilly, February 28th.
VERNON HAZEL.

[It is very interesting to note the fact that Mr. Fox Talbot, the actual inventor of silver printing and of the negative process, was the first to give a practical application to Mr. Mungo Ponton's discovery of the photographic properties of the chrome salts. It would not be fair, however, to overlook the fact that Mons. Becquerel had pre-

viously taken up Mr. Ponton's process, and ascertained that the action of light in this method rendered insoluble the gelatine or other sizing matter in the paper sensitised by a salt of chromic acid, and that M. Poitevin was the first who actually employed these reactions in carbon printing.—Ed.]

A CONVENIENT PIPETTE OR DROPPING BOTTLE.

SIR,—I beg to enclose to you, for the benefit of the readers of the News, a little instrument I have found of great service, which has saved a deal of time, and I have no doubt saved a great quantity of silver solution from being wasted. The purpose for which I use it is this: I use it to measure correctly the silver solution when intensifying the negative. As you are aware, in many studios it is done by dropping some of the bath solution off the dipper, or, where there is a special solution kept, it is generally dropped from the bottle; in either way, there can be no certainty as to the amount dropped. I have no doubt many negatives that would have been very good ones have been spoiled by these methods of working. The instrument consists of a piece of glass tube about the thickness of a goose quill, any length to suit; it is drawn to a very fine point, either by the flame of a spirit lamp or gas, and then a very fine hole is made at the point. Now procure an india-rubber test, such as chemists sell for infants' feeding-bottles. Choose one without a hole in it, if you can; if not, just cover the hole up by applying a coat or two of strong india-rubber varnish. Now introduce the wide end of the glass tube just into the test, and tie the test on to the glass tube tightly, then varnish the thread or string with a little shellac varnish. Now the instrument is complete, and forms a very fine drop syringe. To use it, keep your silver solution in a bottle according to the length of the drop tube described above. Place the tube in the solution (I always keep mine in it), press all the air out of the bulb formed by the test, then allow it to fill by taking the pressure gradually off, when it will fill the tube with the solution, which will not drop out until some pressure is used with the bulb, when it will drop, and may easily be counted; so that any person using it can regulate the quantity of silver solution to a nicety. Hoping it will be found useful by some of your readers, and apologising for trespassing upon your space, I am, sir, yours &c., S. V.

[The pipette enclosed is very handy and useful. Something of the kind has been before described; but this possesses a special advantage in simplicity of manufacture and efficiency.—Ed.]

COLOUR OF CARBON PRINTS.

DEAR SIR,—“A Carbon Worker” is evidently unhappy—evidently a man with a grievance, and the way in which he airs it is neither edifying nor amusing. He is hurt and indignant at “a curious and monstrous kind of monopoly”—at the arrogant claims of the Lambert licensees to “the exclusive right to the best information”—at their “being chary of communicating information,” and many other things.

Why, these people have actually got a special journal, and “Carbon Worker” is not allowed to peep into its pages; and the Autotype Company—he is astonished beyond measure that they should “lend themselves to such short-sighted narrowness.”

This is all very pretty, no doubt; but let us see what it all amounts to. The Lambert-type licensees have made certain payments which entitle them to certain privileges—special times, special materials, special information from the Autotype Company, special instruction—and they receive monthly, as a private communication, a journal containing whatever is new or interesting relative to the process of chromotype printing; in addition, they are entitled to a pecuniary benefit in a reduction in price of all tissue they purchase.

Can "Carbon Worker" show cause why he should participate in these advantages? Has he paid his fee, and not received his *quid pro quo*? or does he decline to pay his money, and still expect these advantages? "Carbon Worker" does not like Lambert purple, "the colour is not good in any sense." Well, perhaps not; the fox said the grapes were sour when he could not reach them; but he knows perfectly well that the very colours that he names as good are open to him; *de gustibus non est disputandum*, he need not attempt to set up his dictum as a standard of good taste.

"Carbon Worker" could hardly be a worker and not know that the Company have for years supplied (to anybody who chose to purchase) two tints, which correspond so closely to his description, that one might have supposed he was actually quoting the Company's price list. He mentions a "rich brown" and a "rich warm black;" the price list gives one colour as "producing a rich brown tone," another as "a rich black, slightly warm in colour." Wherefore this feigning of ignorance?

And now one word as to Lambert's licensees being chary of giving information. It would not be difficult to show that most of the articles that have appeared in the journals lately have been written by disciples of Lambert. Strangely enough, one of the very men "Carbon Worker" thanks (Mr. Witcomb) is a Lambertian man—no one will deny the value of his many contributions. Mr. Braybrooke, whose paper was read before the West Riding of Yorkshire Photographic Society, is the chief of the staff at Mr. Sach's establishment at Bradford and one of the most successful chromotype workers in England, or out of it. If Mr. Wellesley Turner is not a licensee, he certainly seems to know as much about the matter upon which he treats as if he were one. Upon what ground does "Carbon Worker" rest his charge of "petty exclusiveness" and illiberality?

For the future let "Carbon Worker" so marshal his arguments with temper and moderation, so put forth his facts as to be in accordance with the truth; then shall he obtain the sympathy and approval of your readers, and avoid the reproaches of

NEWSMAN.

MEDALS NOT WON.

DEAR SIR,—Your correspondent "Ton Don" should take a run down to Brighton to see a very novel use of medals. The honest photographers of this town, whose "withers are unwrung," will not win at the following remarks, namely, that there is one among us who has the temerity to show a cluster of medals in his shop window, one of which was struck years before he had ever exhibited a photograph.

What would happen to a man in the army if he sported the medal of a deceased or retired officer for a battle fought before he became a soldier? I think, with "Ton Don," the question is very important of how to protect true merit: will some of your readers think this over? And I should be glad to know if any other photographer can tell of such an instance as the above.—Obediently yours, H. POITERS.

Brighton, March 20th.

P.S.—Cannot a Society be got up to manage such matters?

SAYINGS BY MEN WE KNOW.

SIR,—Mr. Nelson K. Cherrill is saying that "new laid eggs will make albumenized paper as permanent as carbon tissue."

Mr. Bovey is saying: "I wish it was true."

Mr. Anthony Rivot is saying: "Pity, 'tisn't true."

The Autotype Company is saying that "M. Lambert is accompanied by his friend and coadjutor Mr. Sarony Lambert;" and that "he is an able negotiator."

Jo. Vestris is saying that Mr. Sarony Lambert is not the only "able negotiator" he knows.

Mr. J. K. Sawyer is saying that "it is not to be expected that chromotype licensees will give the results of their trials and experiments to the world at large."

Mr. George Croughton is saying: "Chromotype licensees are nothing to give."

Mr. A. Wellesley Turner is saying: "Anybody can produce good work by following out my instructions."

Fry and Co. are saying: "Turner's papers are full of instruction; but a day with us is worth ten times the money we charge for demonstrations."

Mr. Higginson is saying: "Chromotype for ever."

Mr. James Hughes is saying: "Higginson beats Lambert."

Mr. Ayton (of Edinburgh) is saying: "I have relinquished my Lambertype exclusive rights out of pure pity for the poor photographers of Edinburgh."

The Autotype Company is saying: "If the other exclusive licensees don't come to terms like Mr. Ayton, we must start the £5 Autotype dodge once more."

ONE WHO HAS LISTENED.

EXHIBITION IN PARIS 1878.

DEAR SIR,—Having applied for space in the coming Paris Universal Exhibition of 1878 for large architectural photographs, &c., I find that wall space, in the shape probably of screens, will have to be provided by the exhibitors, either singly or in concert. As applications were requested to be sent in by this day, it is possible that English photographers have already agreed upon concerted action for this purpose. Can you inform me, and, perhaps, other intending exhibitors, whether such is the case; or, perhaps, some correspondent may be able to direct us what to do in this matter.—I beg to remain, sir, yours truly,

W. H. WHEELER.

[No special or concerted arrangements have been made by photographers, so far as we are aware. We will endeavour to ascertain if anything in excess of the general arrangements announced is likely to be made by which photographers may benefit.—ED.]

RAPIDITY IN CARBON PRINTING.

DEAR SIR,—Sir Thomas Parkyns having taken umbrage at my remarks on his description of Mr. Witcomb's rapid method of working the Lambertype process, proceeds, "in his capacity as a juvenile boxer, to hit hard in the dark." I beg to parry and counter. I believe these are the terms used in fistic parlance. I must first admit my error as to the time expended in producing the prints in question, which I should have stated as seventy-seven minutes, instead of sixty-seven. The negatives were placed in the frames, exposed three-and-a-half tints, transferred to the collodionized glass, developed, passed through the alum bath, dried *slowly*, moistened again, the transfer paper applied, and again dried *slowly*. These slow dryings bother one exceedingly, and as Sir Thomas declines to answer any anonymous correspondents in future, can any of your numerous readers furnish more light on this subject? Does slow drying mean ten minutes, or one hour, or what time? I find at this time of the year, if the prints are required to be stripped from the glass with full gloss, from twelve to twenty-four hours are required.

I have this day gone through the process full tear, and managed to get a print off in two hours and five minutes from starting, but I had to dry rapidly at a fire-rose fire, and the result is imperfect from too much hurry. As to exposure, I find that with the Autotype Co.'s actinometer, three tints in full sunlight require ten minutes; in the shade three tints require thirty minutes, and in a glass printing house three tints require fifty-five minutes.

I am not a Lambertype licensee, although I have a quantity of Lambertype material, purchased from those who cannot work the process satisfactorily; but I can make as good prints by "Autotype Process only," which Sir Thomas suggests is not one of the perfected processes.—I am, dear sir, yours very truly,

H. W.

Talk in the Studio.

DEALING WITH PHOTOGRAPHIC TRAVELLERS.—Referring to the case recently tried in the County Court at Lynn, a correspondent wishes to caution provincial photographers, he him-

self having been victimized. The traveller obtained goods which were to be paid for by goods supplied by the firm which he represented. The goods arrived, with an invoice from the firm, which had to be paid, whilst the goods obtained by the traveller remained unpaid for. Provincial photographers will do well to be cautious how they enter into similar somewhat irregular transactions.

RETOUCHING LEAD.—We have been favoured by Mr. Lafayette Harrison with examples of an American aid to fine retouching in the shape of fine pointed pencils of metallic lead. The "Boss retouching lead," as it is called, receives and retains a finer point than the ordinary plumbago pencil, and permits much finer work and higher finish. A pad having two sides, with a sanded surface of different fineness, is used with the lead, and readily gives it a fine point. We commend this pencil to our readers, as it seems efficient and cheap.

THE NEW PHOTOGRAPHIC ATTACHEE.—This is a clever little contrivance introduced by Mr. Woodbury, and to be obtained of the Sciopticon Company. It is one of the most useful little contrivances we have seen for a long time. Its object is to fix mounted photographs and other cards in albums, scrap-books, &c., or to larger mounts. It forms an ornamental corner for holding the card, two thin brass ends passing through the scrap-book leaf, and turning up at the other side, holding the card firmly by the four corners, and giving an ornamental effect rather than detracting from the neatness of appearance.

To Correspondents

••• To AGENTS AND ADVERTISERS.—Next Friday being Good Friday, the PHOTOGRAPHIC NEWS will be published on Thursday, March 29th. Advertisers should send in their Announcements not later than Wednesday, March 28th.

P. B. R.—Your enclosure is not a carbon print at all, and unless you are unconsciously inexperienced, you could scarcely think it was so. It appears to be a piece of carbon tissue which, having been placed in contact with a negative whilst moist, has torn a portion of the negative film away on attempting to separate them. In placing a piece of tissue, consisting of gelatine or glue, in contact with a negative, it is imperative that the tissue should be quite dry. It is very wise, for beginners at least, to adopt the precaution suggested by Mr. Swan, always to brush the surface of the tissue over with some powdered French chalk as a preventive of sticking to the negative.

J. B.—You can obtain the fullest information of the Autotype Company, Rathbone Place. You cannot work the carbon process professionally without a licence to be obtained of the Company. The question whether it is worth while to purchase a licence for a small town, and which licence, is one which you can only decide satisfactorily for yourself. It is our impression that it will pay all professional portraitists to do so, as it will, without doubt, bring an extended connection, and the carbon prints command higher prices than silver prints.

C. F. M.—We should select the second on your list. Having a shorter focus in relation to its aperture, it will be the most rapid.

ORUS.—The officials at Stationers' Hall do not conduct business by correspondence. Personal application must be made by some one. A copy of the work to be registered must be taken, and the fee paid. That is all.

DAVE.—A mixture of size and lamp black is generally used for blacking the inside of cameras. Or black paint with very little oil, turpentine being used instead, may be employed.

INQUIRER.—We cannot say whether it is precisely the same edition or not. In substance it will doubtless be the same; but it is probably a new edition since the date you name.

G. F. SUBSCRIBER.—A few weeks ago we devoted an article to the subject. It describes the use and value of reflecting screens in lighting the sitter. We believe it is a useful pamphlet; but whether it is worth the money to you must be decided by yourself.

B. G. F.—We presume that the use of barytes in the bath did not become common when Dr. Vogel first suggested its use, because many photographers did not think their baths contained sulphate of silver. There is danger of using excess of nitrate of barytes in the bath, as, being a somewhat insoluble salt, it might be precipitated by the accumulation of nitrate in the bath, and, by its precipitation, produce the pinholes it had been originally added to remove. Nitrate of barytes is soluble in eight parts of cold water. This is, however, the limit of its solubility, and some samples are less soluble. It is, moreover, very easily precipitated from its solution by alcohol. Although photographers are not likely readily to add sufficient to oversaturate the bath, it is well to keep very far on the safe side, especially if the free addition would tend to produce offensive hardness in the negative.

A. H. FAX.—You are right in conjecturing that the use of the term "yolk of an egg" is an error. It should have been "white of an egg."

M. G.—As a rule, all objects in the extreme distance will be sufficiently in focus when foreground objects are in focus; but this is affected by conditions of lens and aperture. The distance beyond which all objects will be in focus depends on the aperture as well as the focus of the lens. It is calculated that with a lens of one-inch focus, and an aperture of one-fortieth of that focus, all objects beyond a distance of four feet will be in focus. Following the same calculation, and adding four feet for each inch of focus, you may ascertain the distance with any lens. Thus, with a lens of ten inches focus, and a quarter of an inch stop, all objects at a distance of forty feet and upwards will be sufficiently defined.

J. C. STENNINO.—We procured the *Builder* of the date mentioned, but could not find any notes of the lecture.

A. YOUNG AMATEUR.—We always avoid the use of acetic acid in the nitrate bath, as it is not necessary, and very difficult, if not impossible, to eliminate without throwing down the silver. The best plan, when excess of it has been added, is to dilute with more neutral nitrate bath. 2. The recommending fresh hyposulphite solutions for fixing is to secure the use of a fresh quantity every time. It does not take any harm from being kept in solution, but there is always risk in using it over and over again. You may, with propriety, keep a stock in solution ready for use, but avoid using the same quantity over and over again. 3. You cannot ascertain the strength of a silver solution without apparatus. 4. Ordinary glazed earthenware would not be safe for boiling down a nitrate bath. Some kinds might possibly answer, but in others the glass would crack. As a rule, a porcelain vessel would serve, but it is much safer to use a proper evaporating dish. The vitreous ware of Edwards and Son, of Burslem, kept by most photographic dealers, answers admirably. 5. In sunning a bath, it may be exposed in a bottle, but it is better in an open dish.

SAM. VERHAEGHE.—Many thanks.
Several Correspondents in our next.

METEOROLOGICAL REPORT FOR FEBRUARY.

BY WILLIAM HENRY WATSON, F.R.S., F.M.S.

Observations taken at Brayton, near Whitby, 35 feet above sea-level.

Date.	BAROMETRIC PRESSURE.			TEMPERATURE IN THE SHADE.			REMARKS.
	Morning.	Noon.	Night.	Morning.	Noon.	Night.	
1 28 10	30 72	28 71	46°	49°	48°		Showers of small rain a.m. and p.m.
2 28 64	29 83	29 69	48	48	48		Rain a.m. and p.m. Windy
3 29 70	29 79	29 70	46	45 5	43		Hail and rain a.m. and p.m. Windy
4 29 80	29 92	30 01	42	45	44		Fair and bright
5 29 90	29 91	29 99	45	48	46		A little rain this morning. Fair, but gloomy the rest of the day.
6 29 93	29 91	29 84	48	48	48		Small rain a.m. and p.m. Foggy.
7 29 83	29 89	29 94	47	49 5	45		Fair, generally sunny
8 29 94	29 88	43	—	44	44		Fair, generally sunny
9 29 91	29 86	29 62	44	47	48		Rain this afternoon
10 29 85	29 55	29 04	47	50	47 5		Rain this evening.
11 29 50	—	29 66	45	—	46 5		Rain early this morning.
12 29 32	29 40	29 42	48	46	46		Rain early this morning. Fair and sunny the rest of the day.
13 29 46	29 50	29 67	46 5	48	41 5		Fair, generally sunny
14 29 67	29 67	29 67	50	54	48		Rain early this morning
15 29 8	29 42	29 44	48	—	44 5		Rain morning and evening
16 29 48	29 57	29 61	43 5	45	45		Showers p.m.
17 29 77	29 61	29 66	43	47	46		Rain this evening. Fair and sunny the most of the day.
18 29 80	29 80	29 73	46	48	42 5		Rain this morning and evening
19 29 64	29 53	29 00	42	44	48		Rain at night with strong wind. Moon
20 29 10	29 24	29 47	40	45 5	40		Rain early this morn., showers this afternoon
21 29 76	29 79	29 92	36	42	34		Fair and sunny at 7.30 a.m.
22 29 99	29 79	29 68	50	39 5	42		Rain this afternoon. Temperature 28°
23 29 84	29 81	29 74	40	46	45		Fair and sunny. A few drops of rain at night
24 29 47	29 30	47	—	45 5	45		Rain a.m. and p.m.
25 29 12	29 16	29 07	41	44	39		Showers about 12 o'clock. Drizzling rain this evening
26 29 24	29 30	29 61	34	40	29		Fair and sunny
27 29 63	29 7	29 34	28	29	29		Fair, generally gloomy. Rather windy
28 29 06	29 11	29 18	26 5	37	25		Fair and sunny

Notes.—Many of the early spring flowers are now in bloom, clearly showing the mildness of the season. We, however, had one or two days of sharp frost, as will be seen by referring to the foregoing.

The Photographic News, March 29, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO PHOTOGRAPHS OF BY-GONE CELEBRITIES—A GENERAL MAID-OF-ALL-WORK

Photographs of Bygone Celebrities.—With all the portrait publications that have appeared, and are appearing, there is not one that has given its readers a series of a nature which they could not otherwise easily procure in another way. It is true that the periodicals to which we allude have given photographic portraits to the public at a much cheaper rate than the pictures could have been otherwise obtained, and moreover the latter have been printed by a permanent process; but something more than this might have been attempted. Following in the wake of *Vanity Fair*, and publications of a like character, the *Figaro*, *Programme*, the *Theatre*, the *Programme*, *Men of the Time*, and *The Portrait*, have been content to give their readers portraits of ladies and gentlemen more or less celebrated, the negatives of whom are doubtless easy to secure. We think they might have given us something more than this. There are many celebrities who have lived since the days of photography, but whose features are fading from the remembrance of some of us, and have never been seen by the rising generation, whose portraits, especially if printed by a permanent photographic process, would be particularly welcome. We need cite but a few names. There is Thackeray, for instance, of whom many good photographs were taken, although such are rarely seen now-a-days; Macaulay, whose image would be eagerly sought for by many; Wellington, of whom doubtless there exists a Daguerreotype or two, if nothing else from which copies might be taken; the late Prince Consort's picture is another that would be in demand. And then there are many in the domain of science, beginning with Cuvier and Fox Talbot, of whom portraits are to be had that could soon be vulgarised. We shall of course be met by the objection that such pictures as these are rare, and very difficult to obtain; that permission to copy them would cost a very large sum of money; and that therefore the publication would be unremunerative. But all these arguments should have little weight with enterprising publishers. Of course, if portraits are published at a few pence each, we can well understand that little profit will attach, unless very large editions are sold; we also comprehend fully that if publishers can get their negatives for nothing, they prefer to do so, as then their takings are all profit. It is nothing new to suppose that a photographer need not be paid for his trouble, and consequently the reason why we are treated with so many pictures of the *dis minores* is very apparent. If photographers would only lend their negatives for the purpose, no doubt we should have seen some of the celebrities we mention published ere this. Unfortunately photographers want to be paid for their work, and the consequence is that the public do not get the opportunity of purchasing what they would most prize. A photographer might require twenty or thirty pounds for the use of a negative of Thackeray or Macaulay, whereas one of the renowned Miss Boventine can be had for nothing. But then the public, somehow, get tired of the latter's portrait, in every variety of dress and undress, and no doubt hold a few pence quite enough to pay for it. It would be different, we think, if it were a question of such portraits as those of Palmerston, Cavour, Alexandre Dumas, Wellington, Macready, to name a few of those at random whose photographs are comparatively rare. A fair price would never be refused for portraits of such worthies, and the extent to which they would be sold would realize a sufficient margin of profit, after paying the owner of the original a good bonus. Even in the case of people already possessing photographs of the celebrities in question, the pictures in many cases have faded or become discoloured,

and collectors would only be too glad of the opportunity to replenish their albums with fresh copies, especially if, as we have said, a permanent process were employed in the printing.

A General Maid-of-all-Work.—Photography has oftentimes been termed the handmaiden of science, but it would be hard to say in what connection our art is not used now-a-days. Colonel Baratti, the editor of an Italian journal devoted to photographic literature (the *Camera Oscura*), which has, however, of late ceased to be published, cited an instance a little while ago of how he employed the camera in the art of gardening. He had a choice fruit tree which required pruning, but hardly trusted himself to do the work. He had a friend, however, in Florence, who bore a great reputation for such matters, and consequently decided upon taking advice upon the subject. The Colonel photographed the tree, sent the picture to his friend in Florence, and in a few days received it back properly pruned; the rest he did himself. Here is an example out of many, and affords a good sample of what can be done by a happy employment of the camera. It is a common thing with West-end hatters to have their stock photographed, and a purchaser in the country has simply to send his number to town and specify which of the pictures pleases him most, in order to receive back the kind of head-gear he wishes to carry. Photographs showing the manner of wearing the hair we have also seen, so we may suppose hair-dressers adopt this method of demonstrating the various *coiffures* in fashion. One of these days we shall have tailors employing photography in the same manner. Army tailors, by the way, do so already, and we remember, a few years ago, to have seen a series of pictures, executed, we believe, at the Woolwich Photographic Establishment, showing the cut and facing of the various tunics throughout the army. Great stress is laid, as our readers know, upon strict uniformity in soldiers' clothing, and on a recent change of costume it was decided to forward to each commanding officer of a regiment a photograph of the "regulation" tunic. In this inexpensive way all those in authority were properly apprised of the changes that had been decided upon. We have no doubt that tailors other than regimental ones will avail themselves of the same plan. There are many people in the country, on the Continent, and in distant Australia, who wear no other clothing than that made in the metropolis, and transmit their orders regularly to Bond Street or Saville Row to be supplied with apparel. Here photography might be employed to far greater advantage than lithography or wood engraving for giving an idea of shape or pattern, and the same holds good with ladies' and children's costumes. The difficulty, probably, would lie in securing models in conformity with the taste of the tailor or dressmaker, for these, we hold, would be somewhat difficult to please. The main drawback to the adoption of photography by tradesmen in general would be, however, the circumstance that it leaves no room for romance. The beautifully illustrated catalogues which show magnificent furniture at low prices, ornamental fenders for eightpence, and elegant arm-chairs at ten shillings a piece, would cease to exist if photography came into general use. We do not say it would be impossible to deceive even with the camera, but at any rate an article would have to be in existence before it is photographed, and such is evidently not the case with many "fancy" articles now-a-days.

THE NITRATE BATH: ITS DEFECTS AND RESTORATION.

BY JOHN SPILLER, F.C.S.*

THE treatment of the nitrate bath has so often formed the topic of discussion in the photographic journals, that it would appear a task of some difficulty to say anything new

* Read before the Photographic Society of Great Britain.

upon the subject, and it is rather with the view of collating the scattered items of information than of contributing fresh matter, that I venture to introduce the subject once more to the notice of the members of this Society. My effort has been chiefly directed to the examination of certain deposits, kindly furnished me by Mr. H. J. Burton, of the Autotype Company's Works, and by Mr. Frederick York, in the hope that the chemical results arrived at may point to the origin of some, at least, of the defects encountered in working on a large scale, for it is manifest that the more limited operations of the amateur do not offer the chance of so fully disclosing the nature of the changes brought about in the process of sensitizing the collodion plate.

Before specifically describing these results, I propose to remind you briefly of the chemical reactions involved, which may be stated somewhat as follows: Collodion composed of one or other of the known qualities of pyroxyline, dissolved in ether and alcohol, and sensitized with the bromides and iodides of potassium, ammonium, or cadmium, is, after partial evaporation in the air, brought into contact with an aqueous solution of silver nitrate, charged nearly to the point of saturation with the bromide and iodide of silver, whereby a sensitive coating of bromo-iodide is formed within the texture of the collodion film, and this remains moistened with the excess of bath solution. By repeated employment it is manifest that the bath becomes in time *fully* saturated with the haloid salts of silver, and contains, besides considerable quantities of alkaline (or cadmium), nitrate, together with ether and alcohol; and, in addition, certain extraneous matters derived from impurities in the iodizers employed. Beyond these we may now expect to find traces in the bath, arising from the use of certain "organifiers," which are often intentionally prescribed as helps to sensitiveness when the plate is being exposed in the camera.

All goes well for a time, but after a longer or shorter interval these secondary compounds accumulate, and begin to exert their special action upon the plate, particularly when, by frequent use, the proportion of silver becomes sensibly reduced. For every plate immersed, an amount of potassium (or cadmium) nitrate equivalent to the salts of silver removed, must inevitably be left in the bath, with also increasing amounts of ethylic compounds and other organic matters. Hence has risen the recommendation to use two or more baths in succession, to overcome the disturbances induced by the first immersion, and I cannot see any valid objection to this mode of working. Mr. J. Brier, jun., proposed such a plan in the YEAR-BOOK OF PHOTOGRAPHY for 1876, and there are earlier suggestions to the same effect. By the slow oxidizing action of silver nitrate upon ether and alcohol, acetic and glycollic acids may be formed; also possibly oxalic, picric, and fulminic acids may exist or be generated from certain organic impurities present in the pyroxyline of the collodion. Mr. Warnerke tells me that two years ago he met with a remarkable instance of the formation of fulminating silver in the nitrate bath, but none of the deposits I have recently examined show the least indication of detonating properties. Mr. York, Mr. Brooks, Mr. England, and others have recorded the occurrence of explosions happening during the process of evaporation to dryness, or subsequent fusion in order to recover the silver from an unserviceable bath, but we must remember that deflagration may always be looked for when silver nitrate is fused with any kind of organic matter, and, in some instances, glycerine may have been intentionally added to the bath during a period of unusually hot weather, and this circumstance, afterwards forgotten, might give rise to an explosion when the attempt was made to recover the silver by fusion. I have looked carefully for oxalic acid, but never yet found it, although acetic acid, and possibly aldehyde and nitric ether, must occur as oxidation products derived from the ether and alcohol. These bodies give rise to the peculiar smell always apparent in a well-used bath.

Another circumstance which recent examination has fully demonstrated, is the frequent occurrence of sulphate of silver as a bath deposit—a fine example of which has been sent to me by Mr. H. J. Burton. It is in the form of feathery needle-shaped crystals, almost insoluble in water, and separating out whenever a strong nitrate bath containing it is diluted with water. Its origin may be traced, first and foremost, to the iodide and bromide of potassium employed in the collodion, for these salts, as found in commerce, almost invariably give a precipitate with barium nitrate, due to the presence of alkaline sulphate as an impurity. Or, secondly, the sulphate may be introduced with the silver, especially if worked from residues containing sulphide, the metal from which, when acted upon by nitric acid, must necessarily give sulphate. Properly refined silver should not retain any sulphur, but, unless the silver from residues be fused with nitre, I have often found sulphide of silver in the bottom of metal reduced with alkaline carbonates alone, and I am inclined to believe that the presence of gold (so common in photographers' residues) favours the retention of the sulphur. Mr. A. L. Henderson must have been aware of this general occurrence of the sulphate of silver when recommending the addition of nitrate of barium to the bath solution, and all testimony agrees in approving the use of this chemical agent as an addition to the bath, which is calculated to overcome, at least, one fertile cause of pinholes. The late Dr. Maidstone Smith reported highly of it a year ago.* Mr. York now uses it, and several operators have recently recorded their experience in the same terms.

Much curiosity attaches to the startling proposal of Mr. Henderson to add also ferrous to the nitrate bath. This has not been done since Mr. Fox Talbot used for special rapidity an iodide of iron collodion, which necessarily introduces ferrous nitrate into the bath; and it would now be important to know more exactly the proportion of iron to be employed. Mr. Henderson's formula in the *British Journal Almanack*, 1877, being somewhat indefinite on this head; two drachms of a "solution of nitrate of iron" being described for a fifteen-ounce bath, with ten grains of the barium nitrate added. When making experiments at Woolwich some years ago, I was astonished to find that the reducing action of ferrous salts was, after all, very imperfect, for it was possible to expose mixed solutions of iron and silver to sunlight for many hours without complete reduction being effected. Always some silver remained in solution side by side with the ferrous salt, and with the knowledge of this fact, I think the new suggestion well worth a trial.

Another method of clearing the silver bath when it begins to show a disposition to form pinholes is to treat it with a very weak solution of pure cyanide of potassium. Mr. A. Borland gave exact details in the YEAR-BOOK for 1876, and Mr. H. J. Burton has carried out the same idea with good effect. One of the silver deposits obtained in re-working a bath at the Autotype Company's establishment consisted mainly of the cyanide of silver in beautiful nacreous crystals, and this led me to enquire whether such a process had not been employed, when Mr. Burton kindly replied that he had often used cyanide of potassium, as he "finds it improves the sensitiveness of the nitrate bath, and gives negatives of very great delicacy." Here, again, we have an instance of a mild reducing agent being added directly to the bath solution, giving rise to the precipitation of a small quantity of cyanide, which carries down with it the excess of iodide of silver. In the early days of photography, M. Le Gray used cyanide of potassium in the wax-paper process as an addition to the iodizing salts, but much in the same way that the fluoride was prescribed, which we know to be altogether inoperative; the idea seems to have emanated from the desire to mix up together all the haloid salts of silver on the chance of the best

* YEAR-BOOK OF PHOTOGRAPHY, 1876, p. 67.

results being obtained by one or other of the many possible combinations.

The mode of sunning the bath with or without a trace of chloride cannot be made available in the winter season, and there is then the acidity to be corrected. A good account has been given of the method of partial precipitation by citric acid, or an alkaline citrate, which is said to carry down with it the excess of argentic iodide; but this mode of proceeding I have only used in connexion with the printing bath, where it answers admirably. For restoring a disordered negative bath, the common practice is, as we all know, to dilute the solution with an equal bulk of distilled water, filter off the precipitated iodide, and make up the strength again with fresh crystals of nitrate of silver; but this process defers only for a time the evil complained of, and is not considered an altogether effectual remedy.

The general conclusion which blends best with all the recorded facts would seem to point to the use of potassium cyanide, added in quantity sufficient to produce a permanent precipitate in the solution, and then to add barium nitrate in slight excess, so that all the sulphate and excess of iodide may be removed with one filtration. If cyanide of barium could be had commercially, a solution of this salt containing within itself the necessary ingredients, would at once accomplish all that is desired to bring about the rectification of a disordered bath.

REMARKS ON THE SILVER BATH.

BY F. YORK.*

I AM not one of those happy individuals who never get into trouble with the nitrate of silver bath, for this happens very frequently, not from freaks with ethyl compounds, but from exhaustion. Last season I worked in comparative comfort. I found that nitrate of baryta was a panacea for a disordered bath. My mode of treatment was to add a grain of this salt to each ounce of solution, boil it for ten minutes, dilute to its proper strength, expose it to sunlight until the bath in use gave out.

I found that a bath after repeated treatment in this manner produced clean but weak negatives, requiring double the exposure. I concluded that the best plan was to reduce it with copper, or, as Captain Abney expresses it, to make a new bath out of an old one. I have sent some of the solution, after reduction, to Mr. Spiller, thinking he may find something not reduced by the copper, which would enlighten us. I attach so much importance to the baryta salt as a specific, that I am most anxious to know its chemical action. We are told that a bath giving pinholes, or, as it is commonly called, a sandy bath, arises from super-saturation with iodide and bromide. This is, of course, a reasonable conclusion, for by diluting it with water, iodide of silver is precipitated. I have used a bath so thoroughly saturated that when poured out it was quite yellow with iodide.

Fulminate of silver has been suggested as the cause of pinholes. I am not prepared to argue this point, but think it not improbable that such a salt is formed. I find that fulminate of silver consists of silver, oxygen, hydrogen, and nitrogen; the fulminate of Leibis is a cyanate of silver; the cyanogen for the production of the cyanic acid being derived from the carbon of the alcohol, and the nitrogen of the nitric acid. An old silver bath contains all these elements. One of the peculiarities of an old bath is, that after standing a few days a crop of numerous transparent needle crystals form on the dipper and sides of the bath. I have seen them a quarter of an inch long. I once collected a small phial full, but cannot find it at present. This is unfortunate, as Mr. Spiller may have detected their composition. I never get them now. These crystals are considered an iodo-nitrate; is it so, or are they fulminate?

* Read before the Photographic Society of Great Britain.

The usual mode of treating a bath in this state is to dilute it, filter out the precipitate, add fresh nitrate of silver to make it the proper strength, or boil it down to that. I have found the nitrate of baryta remove this grievance most effectually. What is the cause? I am unable to do more than offer suggestions. With regard to the fulminate theory, I am induced to think there is some foundation for its presence, for I have often found, when fusing an old bath, a series of sharp detonations when stirring it. I have noticed this more particularly with baths in which cyanide of potassium has been used as a corrector. I am quite satisfied in my own mind of the value of nitrate of baryta in reducing these crystals, and think we ought to know its chemical action. Is it possible that an oxalate of baryta is formed? For I find in the *British Journal* that Mr. Williams, of the firm of Hopkins and Williams, discovered in the residues, after the distillation of old collodion, as much as five grains of oxalate of lime to each ounce of collodion distilled. This is about the weight of the iodizing salts used in each ounce of iodized collodion. Is it possible, the Editor suggests, that those crystals may be oxalate of silver?

I should also like to be informed why the silver reduced from bath solution by copper when converted into nitrate, and a bath made from it, that it should be still saturated with iodide of silver. This salt does not appear to be got rid of after refining. I once precipitated some old baths as chloride, and sent it to the refiners. The metal was returned. I made it into nitrate of silver, and, strange to say, that when I dissolved it in distilled water it turned yellow, as though iodide has been added to it. I tried it for printing, and had great difficulty in toning, as though iodide were present.

The Editor of the Society's Journal has the following note on the above:—

"It will be noticed that Mr. York calls attention to the fact that when the silver from an old bath is precipitated by the addition of metallic copper, the silver iodide is left unreduced. In making a new sensitizing bath from an old one this is of no importance, as any excess of iodide can be filtered out; but it is well worthy of notice that the reduction of the salts of silver to the metallic state is not completely effected by copper. Neither the iodide, the bromide, nor the chloride of silver, are decomposed by it. In fact, these haloid salts of copper are partially or entirely decomposed by soluble salts of silver, the haloids of the latter resulting from their contact with it. If it be desired to reduce the iodide to the metallic state, it is a better plan to throw granulated metallic zinc into the old bath, slightly acidulated with either sulphuric or hydrochloric acid. This will reduce all the silver salts to the metallic state. To get rid of any excess of zinc, acid must be added till all action ceases, and the precipitated silver must be well washed. If hydrochloric acid have been employed, it is advisable to rinse with ammonia before the final washing.

MR. SWAN'S PATENT.

BY JOHN URE.*

WITH the view of eliciting discussion on a subject I deem of considerable importance to our profession, I beg to submit the accompanying suggestions, which, if you deem advisable, may be read to the members. You are, no doubt, aware that Mr. Swan's patent on the carbon process expires next February, and the Autotype Company will doubtless use every effort to obtain an extension of the same, and thus prevent the improvements that would be certain to follow from healthy competition if the matter were thrown open to the profession.

The carbon process has already raised considerable controversy in the journals, and I would further remind our members of the motion, passed last season, binding us to

* Read before the Glasgow Photographic Association.

use every means to prevent a renewal of the patent. My sole reason in taking this course is that the process may be untrammelled, and improvements effected in the manipulation, instead of being worked by a few licensees, as at present—some eight or ten in Glasgow, and only one or two practising the process, and that to a very limited extent. Now, as the Autotype Company seem to aim at the establishment of a monopoly of this process by buying up all the patents connected with the subject, and as Mr. Swan's patent is the basis of all the others, I would humbly suggest that it is our duty, seeing it has no valid claim to originality, to oppose by every legitimate means its extension, as it is well known that many others worked the process before the date of Mr. Swan's specification. Proof of this can be produced, written and otherwise, to convince the Lord Chamberlain that the subject of the patent was not new, and that the Autotype Company in this monopolising spirit were seriously impeding and hurting the advancement of the art.

In support of this view we have the written testimony of Fargier, Ponton, Poitevin, and Blair, besides many others, who had previously used the same. But, in addition to this, there is another flaw in the patent, namely, that in the provisional specification and the final one different principles are mentioned—an error at once fatal and illegal, as decided by the highest law court in the country within the last few weeks in the case of Messrs. Bailey and Son, manufacturing chemists, Wolverhampton, against a person in our city for using an invention for preserving meat, known among butchers here as the "doctor." Now, the only difference in the provisional and final specification is that in the former bisulphate of lime and gelatine is used, and in the latter bisulphate of lime may be used alone. Judgment was given for the defendant, as a case in every respect parallel.

Another reason that should stir us up in the matter is that one of the partners of the Autotype Company was in Scotland the other day endeavouring to buy back the licenses from those who have the right of granting district licenses. Now, what is the meaning of this if it be not to continue the monopoly?

Again, I have been told that proceedings have been threatened against parties who have gone into enlarging for the trade. Now, in the face of these facts, is it not time that we should be getting up proof and a fund to combat these proceedings? If the Autotype Company really consider these patents valid, why do they not at once settle the matter in our courts of law? But I fear they know the weak points too well to trust to the searching examination of a Scottish court.

In conclusion, my advice to all is to work away, for if I thought the process a commercial success—which I do not without further improvement—I would at once adopt the carbon process, and ask permission from no one, as I have worked it before the existence of any of the Autotype Company's patents, and will do so again when more perfect.

ORGANIC AND INORGANIC MATTER: THEIR USE IN BROMIDE OF SILVER SOLUTIONS.

BY J. JOHNSTON.*

To have organic matter in conjunction with bromide of silver, so that it may act as a vehicle for distributing it equally over a suitable surface, is a necessity in emulsion work. The other function, or functions, which it performs not being so apparent as the one already alluded to, the question has been, on that account, often raised as to what action organic, and likewise inorganic matter have on bromide of silver to produce the real or fancied changes attributed to them.

I have always looked upon the solution of the above question as the key to the successful preparation of bromide of silver emulsions, and have, in consequence, given my

attention to it for a considerable time. The conclusion that I have come to is that the property of affinity possessed by the bromide of silver enables its molecules to combine with the molecules of organic and inorganic matter, which possess a similar property of affinity, and in such a degree the combined molecules just neutralize the affinity of each other, the result being that a molecule of bromide of silver with its equivalent of matter, either organic, inorganic, or both, remains in a neutral state as regards its affinity for another molecule of bromide of silver. This conclusion has been arrived at by observing the formation of bromide of silver, and certain peculiarities connected with it after its formation.

I now propose to show the nature of my reasoning, and for that purpose will assume a case of the formation of bromide of silver in water. I have selected water, as in it the peculiarities of the affinity possessed by bromide of silver appear in a very decided form.

On adding silver nitrate in solution to a soluble bromide in solution a substance is formed of a pale yellow colour, which, I need scarcely add, is bromide of silver. At the instant of its formation it presents a fine creamy appearance, after which it is seen in a perceptibly granular state, being deposited on the side and bottom of the vessel in which it is contained, and in this condition is unfit for photographic purposes. I have no doubt that these features in the formation of bromide of silver are too often unpleasantly familiar to those engaged in emulsion work. However, I have found them very serviceable in pointing out the means to an end.

The creaminess first observed is always a sign of the silver bromide being in a fine state of division; the granular state which succeeds it is undoubtedly caused by the affinity which the molecules of bromide of silver have for each other. I have thought it necessary to assert this, as much depends upon the fact.

If some of the deposited bromide of silver be examined closely it will be seen to be composed of separate particles, all of which appear to be about the same size, and they, apparently, have no further tendency to increase in size or join with each other; they appear to be in a neutral state, as if some condition of affinity had been satisfied.

Now, instead of a very great number of molecules of bromide of silver being required to join together to produce a state of neutrality in the particle which they compose, only two were required; it is evident that bromide of silver, in a fine state of division, would be the result. But this cannot be done, and even if it could, it is very doubtful if pure bromide of silver in a fine state of division would be photographically more serviceable than it is in the granular state. Here, then, it is where organic or inorganic matter comes to our aid.

In experimenting with ammonia and bromide of silver combined, and subjected to heat, I have been able to increase the affinity of the silver bromide; and, on the other hand, by adding acetate of ammonia and gelatine to silver bromide, and applying heat, I have caused the silver bromide to assume a fine state of division. From these and many other experiments I found that ammonia is a suitable agent for bringing organic matter in conjunction with the molecules of bromide of silver to produce a state of neutrality in them. The action of suitable organic matter on ammonia would appear to be to reduce its affinity to a degree to just produce neutrality in the bromide of silver molecules.

I will show you a sample of bromide of silver in a neutral condition. This bottle contained bromide of silver suspended in the liquid which is now in it, but, being undisturbed for a period of three months, the whole of the bromide of silver has been precipitated. My object in having it in this condition is for the purpose of solving a rather important problem in emulsion photography, which is to separate the soluble and unnecessary salts—which are the products of the formation of silver bromide—from the bromide of silver, without the necessity of having to wash the emulsion,

* Read before the Glasgow Photographic Association.

The experiment will, therefore, answer the double purpose. I hope at the next meeting of the Association to have time to show bromide of silver in the condition already referred to.

ALKALIMETRY.

BY J. CHISHOLM.*

Preparation of the Standard Acid.—Ordinary sulphuric acid, 1 fluid ounce diluted with 7 fluid ounces of water, and the mixture allowed to cool. Weigh 1 gramme of anhydrous carbonate of soda, and dissolve it in about 10 to 15 cubic centimetres of water. Pour the diluted acid into the burette up to zero, and let it drop into the solution of carbonate of soda, to which a litmus solution has been added. Let the acid in the burette drop carefully into a boiling flask containing the carbonate of soda solution till the colour turns red; now boil the flask to expel the carbonic acid. The process is finished if, after boiling, the red colour remains.

In our example we found that 6.4 cubic centimetres by the burette were used to neutralize the carbonate of soda, and we wish to form a solution such that 10 cubic centimetres would neutralize 1 gramme of carbonate of soda. We have therefore the following proportion:

Acid	Water	Acid	Water	Acid	Water
10—6.4=3.6	∴ 6.4	8.8	∴ 200	112	

Equal the amount of water required to make a standard acid solution.

To Test Commercial Carbonate of Soda.—One gramme by weight is treated as above described; and, of course, the less acid used, the more impurities in the carbonate of soda on trial.

For example, if we use only 5 c. c. of the acid to neutralize 1 gramme of commercial carbonate of soda, it would follow that only one-half or 50 per cent. of carbonate of soda is contained in the commercial article, while the rest is impurities. If, for instance, we use 9.1 c. c. of the acid, it would follow that the article on trial contained 91 per cent. of carbonate of soda.

In order to compare the strength of commercial ammonia with the carbonate of soda, we took for our example 10 c. c. of liquid ammonia and used 41.5 c. c. of the acid until the blue litmus turned red. Hence it follows that 10 c. c. of the normal acid would neutralize 2.4 c. c. of ammonia; and as 10 c. c. of the acid also neutralizes 1 gramme of carbonate of soda, it follows that 2.4 c. c. of ammonia is equivalent to 1 gramme of carbonate of soda.

Acid	$\frac{c.c.}{NH_3}$	Acid	$\frac{c.c.}{NH_3}$
As 41.5	∴ 10	∴ 10	∴ 2.4

Therefore 2.4 c. c. of liquid ammonia would be equivalent to 1 gramme dry carbonate of soda.

In another experiment made with commercial carbonate of ammonia, 1 gramme required 11 c. c. of normal acid to neutralize it. Therefore, 0.91 gramme would be equivalent to 1 gramme of carbonate of soda, or 2.4 c. c. of liquid ammonia, all of which will neutralize 10 c. c. of the normal acid.

To simplify the above proportion between the carbonate of ammonia and liquid ammonia, we demand how much liquid ammonia is equivalent to 1 gramme of carbonate of ammonia?

$\frac{gramm.}{NH_4O, CO_2}$	$\frac{c.c.}{NH_3}$	$\frac{gramm.}{NH_4O, CO_2}$	$\frac{c.c.}{NH_3}$
0.91	∴ 2.4	∴ 1	∴ 2.6

Therefore, 1 gramme of carbonate ammonia is equivalent to 2.6 c. c. of liquid ammonia.

How much carbonate of potassa is equivalent to 1 gramme of carbonate of soda?

$\frac{gramm.}{NaO, CO_2}$	$\frac{gramm.}{KO, CO_2}$	$\frac{gramm.}{NaO, CO_2}$	$\frac{gramm.}{KO, CO_2}$
As 53	∴ 69	∴ 1	∴ 1.032

Therefore, 1.3 gramme KO, CO_2 will be indicated by the same quantity of normal acid as 1 gramme of carbonate of soda.

* Read before the Photographic Section of the American Institute.

How much caustic potassa is equivalent to 1 gramme of carbonate of soda.

$\frac{gramm.}{NaO, CO_2}$	$\frac{gramm.}{KO}$	$\frac{gramm.}{NaO, CO_2}$	$\frac{gramm.}{KO}$
As 53	∴ 47	∴ 1	∴ 0.87

How much caustic ammonia is equivalent to 1 gramme of carbonate of soda?

$\frac{gramm.}{NaO, CO_2}$	$\frac{gramm.}{NH_3}$	$\frac{gramm.}{NaO, CO_2}$	$\frac{gramm.}{NH_3}$
As 53	∴ 17	∴ 1	∴ 0.32

That is to say, 0.32 NH_3 will neutralize as much normal acid as 1 gramme of NaO, CO_2 ; but the commercial ammonia contains a great deal of water which you can determine by the specific gravity of the liquor.

ARTIFICIAL LIGHT.

BY JAMES MARTIN.

A short time since I observed in a leading provincial newspaper a notice of a new light to be used for photographic purposes, of which I have not observed any mention as yet in the News. It was said to be produced by the combustion of phosphorus with nitrate of potash in such a manner that as the phosphorus burns the nitre melts, and, thus giving out its oxygen, produces a very powerful and actinic light. If this really be an accomplished fact, and not a newspaper canard, the light will be equivalent to what was called in old times, by chemical experimenters, the sun in a bottle, produced by the burning of phosphorus in a bottle of oxygen gas. Its production would become much simplified if it could be produced in the manner stated.

Thinking that some of your readers might like to experiment in this direction, I offer a few hints and precautions for their guidance, feeling assured that if such a light can be produced in a simple manner, it will afford a great boon to photographic art, especially as it could be afforded at a very cheap rate. Phosphorus is sold by chemists in the form of what are called sticks, being pieces about the size and shape of a blacklead pencil. It can be cut with scissors. It inflames at a very low temperature, and, therefore, must be kept under water. Great care must be taken that none of it gets beneath the finger-nails, or it will cause very painful wounds. All experiments with it should be performed in the open air. It is soluble in warm olive oil, and in the proportion of a drachm to an ounce of oil forms what may be termed phosphoric oil; an ounce of which, kept in a four-ounce white glass bottle, will, on removal of the cork, afford quite sufficient light to tell the time by a watch in a dark room. It is harmless externally, and may be written with, or even applied to the skin, without danger. Thus its pale lambent light may be made the source of much wonder and amusement.

Nitrate of potash is sold by grocers and chemists in the form of crystals, also in small cakes and balls. It is too frequently largely adulterated with common salt. This may be detected by dropping a little of the article into a solution of nitrate of silver, when, as your readers will know, if common salt be present, the silver will be thrown down in the form of a chloride. Nitrate of potash is easily melted at a low heat, and can be cast in any shape required.

The experiment I should suggest would be to cast a cylinder of pure nitrate of potash, having a bore down its centre of such a size as easily to admit the insertion of a stick of phosphorus. The whole affair would appear what might be termed a phosphorus candle, the phosphorus representing the wick, and the nitrate of potash the tallow; and I should think that they should be in about the same relative proportions. This can only be determined by experiment. Only an inch or so in length should be tried at first. Place the candle thus prepared in a capacious earthen pan, so that if any burning particles be thrown off they may do no damage. Ignite the phosphorus, and note the result.

THE CARBON PATENTS.

COMMUNICATIONS from various quarters reach us asking for information or advice as to the effect of the approaching expiry of Mr. Swan's carbon patent now held by the Autotype Company. Reference to the matter may at first sight seem premature, as nearly twelve months must elapse before the complete period of the patent has run, and even then there is the possibility of a renewal. As most of our readers know, the full term for which the protection of letters patent can ordinarily be obtained is fourteen years. The first grant of protection is for three years. At the end of this time, on payment of a further fee, the protection is extended for four years more, making seven years from the first date. At the end of seven years, on payment of a further fee, the protection is extended for seven years more, making fourteen years in all. At the end of this period the invention, as a rule, becomes the property of the public. But in certain cases a further renewal or extension of the protection is possible, although it is very rarely obtained. The ground of application for such further extension is generally the alleged fact that the usual time—fourteen years—has been insufficient to permit or secure a return for the capital invested in the commercial launching of the invention. The machinery for granting this extension is somewhat cumbrous. At one time an Act of Parliament was necessary. Now it may be effected by petition to Queen in Council. The application for renewal is made to the Queen, who refers it to the Judicial Committee. The grounds for the application are heard before this Committee, before whom, also, any opposition may be brought and supported by evidence. If a good case is made by the applicant, he may, if the Committee regard his request as not in opposition to public policy, gain an extension of seven years more. The benefit of this power of prolongation was extended, by the fourth section of 7 and 8 Victoria, c. 69, to the assignee of a patentee. The assignee is permitted to apply for extension, although he stands in a less favourable light before the Committee. If he have, however, furnished the inventor funds which have enabled him to complete his invention, this will be regarded as a favourable element in his claim. The proceedings in an application for prolongation commence by inserting advertisements in the public press giving notice of such application. And persons wishing to oppose are entitled to enter a caveat, and to be heard by counsel before the Committee. Where the grounds of opposition are considered by the Committee as frivolous, costs may be given against them. But the costs of such an application for renewal, both to the patentee and opponents, are generally heavy.

A circular letter just received from the Glasgow Photographic Society informs us that they last year appointed a committee to use all means in their power to prevent a

renewal of Swan's patent, should an attempt be made to secure its extension; and the Society has recently appointed another committee, apparently with a similar purpose. It is to watch and take necessary steps, and to communicate with other societies, seeking their co-operation in such opposition. If the necessity arose, something more than the goodwill to oppose would be necessary. As opposition to an application for extension of patent could only be heard through counsel, somewhat extensive funds would also be necessary. Without any private information regarding the intentions of the present owners of the patents, we do not apprehend that there is much probability of an application for the extension of the patent in question, inasmuch as the prolongation of the monopoly at present enjoyed by the Company is already protected by other patents having several years to run.

Swan's patent was dated February 29th, 1864, and will expire at midnight on the 28th of February next year. As most photographers know, its protection covered a certain manufacture of tissue, and a certain mode of operating. The same kind of tissue suitable for transferring is still used, but the mode of working has been superseded. The use of paper coated with india-rubber for transfer purposes has been superseded by Mr. Johnson's method of mounting on an impervious surface without the aid of cement of any kind; and as this method was patented in 1869, and is universally employed, the possession of the patent for this mode of working continues to the Autotype Company the sole possession, practically, of carbon patent rights in this country. The expiration of Swan's patent will put an end to their exclusive right to manufacture tissue, but their power to insist on the use of their tissue will remain as a condition of permitting the use of their other patents. For, we should add, that besides the patent for the cardinal principle upon which carbon printing is worked, the Company possess several auxiliary patents—some for modes of preparing tissue, transfer paper, &c.—as well as the Lambert patents. Even apart from legal protection, only to be secured by costly proceedings, a company in possession of the field, possessing all the advantages of precedence, experience, and prestige, is manifestly in a strong position, and, happily for photographers, it has always manifested a disposition to exercise its powers liberally, and wisely to disarm antagonism by rendering it not worth while to maintain it.

Amongst the numerous questions which have reached us on this subject, we print one on another page in which an enquiry is made in reference to an announcement in an advertisement offering to teach the Lambertype operations, and stating that no license is necessary. We are asked if this is the fact. We can simply state that Lambert's processes are patented, and that, being so, they cannot be worked without license from the owners of the patents. If we are further asked as to the validity of those patents, we can simply reply that a satisfactory answer can only be gained when a case is presented for the consideration of the Vice-Chancellor. If our correspondent ask if such a decision is likely to be invoked, we think he will learn from the Autotype Company that they will have no hesitation in seeking it in case of ascertained infringement.

We do not here enter into any discussion of the observations of some of our correspondents on the obstructiveness of the carbon patents. We are bound to say, from a careful consideration of the facts, that carbon printing has been advanced rather than obstructed by the existence of the patents. The existence of Swan's patent was no barrier to the improvements in Johnson's and subsequent patents. And the existence of a patent rendering possible some compensation for labour, rendered men like Swan and Johnson able to devote years of time, occupied in constant experiment, to rendering practical a process so desirable, yet so hedged round at the outset with difficulties.

SCIENTIFIC CLOUD PHOTOGRAPHS.

THE Astronomer-Royal for Scotland, Mr. Piazzi Smyth, whose photographic operations inside the Pyramids may still be remembered by many of our readers, proposes that a meteorological record should be furnished by photographing the formation of clouds. Mr. Smyth believes that a systematic depiction by the camera of the cloud formations from time to time would be of considerable use as an addenda to other meteorological results, and would aid in arriving at more conclusive results.

To carry on such work, it would be necessary that the meteorological station should be well removed from the murky atmosphere of a town or city, for Mr. Smyth has found that experiments conducted at the Royal Observatory at Edinburgh are materially influenced by interrupting causes of this nature. During the past two years he has experimented at Edinburgh, "in the few and far between opportunities which the almost eternally smoky climate of a great city permit;" and the results he has obtained confirm him in the belief that matter of scientific interest would be afforded by prosecuting the work still further. The Astronomer-Royal for Scotland has succeeded in "photographing clouds with sufficient definition and rapidity to secure much of the detail of their structure, though in rapid current motion and organic change at the time;" and by having recourse to some new arrangements of the optical, chemical, and mechanical parts of his apparatus, he has obtained results "which are probably well worth preserving and publishing."

One particular series of cloud photographs Mr. Smyth mentions as being particularly noteworthy, having been taken during the progress of an eclipse. He tells us that the effect of the eclipse upon the formation of clouds is very clearly shown in photographs, the phenomenon "altering the physical constitution of the earth's clouds for the time being;" a circumstance that "was abundantly, and even grandly, manifested on the photographic plate."

FRENCH CORRESPONDENCE.

M. JANSSEN'S PHYSICO-ASTRONOMICAL OBSERVATORY RECOGNISED BY GOVERNMENT: ITS INSTALLATION AT THE CHATEAU DE MEUDON—A MONSTER DARK ROOM—BLISTERS IN ALBUMENISED PAPER AVOIDED BY AN ALCOHOL BATH—PHOTOGRAPHY AND THE POLICE: EXTENSION OF THE PHOTOGRAPHIC STAFF AT THE PARIS PREFECTURE.

SOME months ago I gave the readers of the PHOTOGRAPHIC NEWS an account of the physico-astronomical observatory which M. Janssen had established at his own expense at Montmatre on a height overlooking Paris. It was only a provisional establishment, a veritable scientific camp, in fact. Indeed, the eminent astronomer, whose name is as well known in England as in France, had merely rented a piece of waste ground, and had there set up the barrack and outbuildings which had served him in Japan, at Nagasaki, at the time of the observation of the Transit of Venus, and which he had taken care to bring back with him. The apparatus at his disposal was new, and well adapted to astronomical purposes, for it had been specially purchased for the Transit of Venus observations; and M. Janssen has made therewith observations of a most important and useful character, the *revolver photographique*, his own invention, being of particular value. Among other things, he commenced here, at Montmatre, to record the history of the sun's disk, taking daily a series of pictures representing phases of the solar orb. I have already spoken of these pictures, which are taken with such precision and of such a size as to render their study exceedingly facile.

An enterprise of this description, the value of which from a scientific point of view must be apparent to all, could not obviously remain in the charge of a single man, and one day or another it was evident Government would be compelled to come to the assistance of the astronomer, especially as the work partook of a national character. The day was not very long coming, for at the end of last

year the observatory was officially recognised, and M. Janssen was nominated director of it. Moreover, the Parc de Meudon was definitely assigned to him for setting up the establishment in a proper and adequate manner. It would be difficult to find a more eligible site than that now decided upon. The fine chateau, which visitors loved so to visit in their excursions around Paris, was burnt at the time of the war, and of it there now remain but the four walls and the magnificent terrace, which has before it a vast panorama of the Seine and the Bois de Boulogne. This terrace seems designed expressly for a platform whence to undertake the exploration of the heavens. Hither M. Janssen has transported his encampment, awaiting the moment until the chateau which is to be fitted up for his work shall be ready to receive its new master.

This week I had the pleasure of visiting the new domain of the eminent astronomer, and I saw, among other things, a large dark room, the interior of which was fitted up as a series of photographic laboratories, arranged with a good deal of ingenuity. The building is of brick, with an acute roof, and has something the aspect of a barn. Inside are partitions of wood reaching half way up, and forming two rows of separate cells, separated by a corridor, into which they all open. Each compartment is illuminated by a window of yellow glass, and there are proper washing arrangements and places for draining the plates, racks, &c., in all of them. The interior of the barn-like building is painted from top to bottom in yellow, and two little yellow doors, one on each side of the building, permit of the entrance and exit of persons without inconveniencing any work that may happen to be carried on. The air warmed by a stove circulates freely above the compartments, and imparts an agreeable temperature throughout. It will be seen from the above that the room is provided for a large staff of assistants, and we may mention that the Observatory will be, besides a post of observation, also an establishment for the instruction of students, who will be able to follow all the operations as they are carried on. All the apparatus which we saw in working order at Montmatre are here set up again, under canvas or wood, upon the Meudon Terrace, and the regular work of the establishment is now resumed after a pause occasioned by the removal. But, as we before remarked, the situation is still only temporary, and the reconstruction of the chateau will forthwith be commenced. When complete, the physico-astronomical laboratory of M. Janssen, which he has taken so much pains to establish, will be one of the most charmingly situated of all scientific establishments.

For some time past complaints have reached me of blisters in albumenised paper during the operation of washing which follows the fixing of positive prints. A provincial photographer, M. Andr  s, has now communicated to me a simple method, which is at the same time an inexpensive one, thanks to which he has been able for some time past to counteract the defect in question. This is the plan he recommends. You pour into a bath some rectified spirits of wine and distilled water in equal parts. After the first washing operation, which follows the toning, the prints are plunged into this bath, which may last a long time; an immersion of five minutes suffices, and then the paper will be seen to be more transparent. At the same time the image assumes a grainy look; but about this one need be under no apprehension, for the appearance will gradually disappear. On coming out of this alcohol bath, the prints should be washed once only, and are then fixed and finished in the ordinary way. To convince oneself of the good effects of this alcohol bath, it is only necessary to plunge the half of a print upon a sample of doubtful paper; it will be seen then that the half that has been dipped into the alcohol bath is quite free from blisters, while the other portion will be attacked by these.

About a year or eighteen months ago I announced, in

one of my letters to the PHOTOGRAPHIC NEWS, the formation of a photographic service in connection with the Prefecture de Police at Paris. Till then, such work as it was necessary to execute for police purposes was undertaken by professional photographers, but, as may be imagined, such a course was found often to be inconvenient, and one or two officials who had some knowledge of photographic manipulation were induced to discharge such duties. They were provided with a laboratory, such as it was, at the Central Police Station of Paris, and notwithstanding many points of an unfavourable character, the staff managed to render some valuable services. Today the photographic department of the Police has been greatly enlarged. As soon as a crime is discovered, the body of the victim is at once photographed, and if it cannot be identified, hundreds of prints are produced of the negative, and distributed in every direction, while the remains themselves are taken to the Morgue. If the guilty is known, and has taken flight, his portrait is procured if possible, and this is also reproduced for distribution; if but suspicion point only to a certain party, the same steps are taken. It is in this way that the Police have of late taken measures which have proved successful in the case of a terrible crime that has resounded throughout Paris for the last month. The services rendered by the photographic staff of the Police in the notorious instances of Billoir and Moyaux have added much to its prestige, and the Prefecture is now about to make more extensive arrangements so as to make further use still of the camera. So far have they gone as to make experiments with a process which enables one to send a portrait by telegraph, in the same way as an ordinary message. I shall return in a future letter to this interesting subject.

ERNEST LACAN.

THE RETICULATION DIFFICULTY.

BY W. E. BATHO.

RETICULATION in carbon prints has occasioned, and will occasion, discussion in reference to its cause and cure. I need scarcely point out that the knowledge of the one does not imply that of the other. You may know the cure without being able to state why it is such, or again the cause, and not be able to suggest a remedy. As this defect "is peculiar to pictures developed on collodionized glass," it seems at least irrational to seek for remedial measures among remedies having no relation to the before-mentioned circumstance. That the defect is a purely mechanical one seems very probable when the simple substitution of a flexible for a rigid support at once removes the evil. In the Company's Manual, the following are given as some of the causes of the defect. First. "The tissue dried too quickly." Second. "The use of a too neutral solution of bichromate of potash." Third. "The collodion not suitable." Fourth. "The tissue allowed to become too limp."

The first of these causes seems to me to depend upon very debatable ground. I have reasons to know that upon several occasions M. Lambert dried his tissue very rapidly, and produced therewith pictures of as fine a quality as can be obtained with the recognized methods. In my own case, with such materials as are at hand at home, I have dried tissue in under two hours, the conditions being a good current of air, and a considerable variation between the wet and dry bulb, showing a dry atmosphere; while such tissue was not so sensitive as another dried slowly, prints were produced therefrom having no trace of the evil complained of; indeed, it is but a few days since I sent two prints produced with these tissues to a friend in the States, one half of each being reticulated, and the other half quite free therefrom. Such diversity in the same prints was produced by the method of transfer employed, hence it does not follow that quick drying gives reticulation, or slow drying an absence thereof.

En passant, I would mention that the use of alcohol to enable tissue to be dried with greater speed is no new in-

stitution, being now nearly ten years old; it is recorded in your volume for 1868, page 497. The method there indicated I have occasionally used, and have overcome the difficulty of the decomposition, indicated by poor keeping qualities, with a liberal dose of ammonia. It may not here be out of place to put on record a circumstance I think I am first to observe, viz., that insolubility of bichromatized gelatine upon exposure to light is not produced when conditions are brought about in which moisture is perfectly excluded.

The second cause of reticulation as given, is "the use of a too neutral solution of bichromate." If by this is meant the use of a solution not acid enough, I may say I have never yet found an alkaline state of the sensitizing bath produce any injurious effects. It was once said to me that it caused decreased sensibility, indeed, to an alarming extent. I have never found it so, and in support of this view may quote M. Lambert, who says, "The more ammonia you put in your sensitizing, the quicker the printing" (see *Philadelphia Photographer*, December 1876). Still I don't think this, but simply that it has no effect on reticulation or sensibility.

The third item—viz., unsuitable collodion—without doubt touches the cause of reticulation in its most vulnerable point. I have reason to know that a support interposed between the exposed tissue and its rigid support of an elastic nature prevents the evil.

The fourth really means the tissue is in too expanded a state. This would also be overcome by the method indicated in treating of the third cause.

In conclusion, attention may be drawn to the varieties in tissue. For the Autotype Company to say all their tissue sent out is good and fit to produce the best work for which they are intended, is simply at variance with fact. No doubt every care is taken to produce uniformity of result, but they do vary, and hence cannot all be the best. The change brought about in gelatine with boiling or continued heating must bring about corresponding varieties in tissue, and certainly is a circumstance not to be over-looked by photographers.

It unfortunately seems to be becoming a practice to snub the labours of "outsiders;" but it may be aptly said, such treatment with the carbon process would betray a vacuity of mind that might well and wisely be made a store room for the history recording the labours of those pioneers upon whose brain-work as a foundation the carbon process of to-day stands firmly erected.

Correspondence.

CARBON PATENTS.

Glasgow Photographic Association.

SIR,—The Glasgow Photographic Association have had under consideration at various times the question of carbon patents. Last year they passed a resolution to use all the means in their power to prevent the renewal of Swan's patent, should any attempt be made to have it renewed.

This year the Association have again had the subject under consideration, and appointed a committee to watch and take any steps necessary; also to communicate with other societies, asking their advice and co-operation.

The committee would now respectfully solicit your advice and co-operation, and will be most happy to hear what your views are, and if you will lend your countenance and support for the object indicated.

Swan's patent expires in February, 1878; its claims are 1, The preparation and use of coloured tissues; 2, The mounting of undeveloped prints obtained by the use of the coloured gelatinous tissues; 3, The re-mounting or transferring of developed prints produced as above described from a temporary to a permanent support.

It may be taken that this patent, or the principle of it, is the backbone of carbon printing as at present practised

(although there are doubts as to its originality); but the patent being removed, the great obstacle to the use of the carbon process and the manufacture of the tissue would be taken away, thereby cheaper and better tissues may be expected to be introduced, and other improvements made in the process.

We believe the licensees, and all others practising photography, are interested that this patent be not renewed.

Our committee will be greatly obliged by you or your Society sending an answer at your earliest convenience.—Yours respectfully,

ALFRED ROBERTSON, Hon. Sec.

37, Glassford Street, Glasgow, March 24th.

[The above letter, although forwarded to the Editor, is manifestly one sent round to individuals and representatives of photographic societies.—Ed.]

SIR,—I was in Glasgow last week, but too late for the Association meeting. It seems there was a great discussion on that inexhaustible topic, the Autotype Company and their patents.

The little photographers and tintypers about the Broomielaw are labouring under the hallucination that they are groaning under an unjust and unlawful monopoly, and that the Autotype Company are "seriously impeding and hurting the advancement of the art." Mr. Urie is the leader of this little band of knight errants. "I produced pictures in carbon twenty years ago, and could do so again. I produced better carbon prints than those of Paton's, and I never saw Lambert," were the remarks of Mr. Urie. The discussion resulted in a committee being appointed "to oppose any application for the renewal of Mr. Swan's patent by the Autotype Company, and to confer with other societies in order to elicit their sentiments, and secure their co-operation."

The spiritualistic proclivities of some members of the Glasgow Association, and the pronounced scepticism of others, is well known, and at an adjourned meeting of this vigilance committee an unexpected scene took place which teased the sceptics and pleased the spiritualists. In conversation Mr. Urie's manifestations of a former meeting were adverted to, which brought a cloud upon the brow of Mr. B——, who at once sent for the medium Duguid, soliloquizing, the while, "This is the night which makes me or for—does me quite."

On the arrival of the medium the gas was turned down, and he having gone through the usual shiverings, the orthodox rap was the sign that questions might be asked. The spirit of every departed carbon experimentalist was called in succession, and all declared that they "detested patents"; all declared that the committee would be successful. Mr. Urie asked "if they might look for any hope of reducing the patents of Johnson, Sawyer, and Lambert?" Whereupon the medium spoke, in a foreign tongue, "*Dabit Deus his quoque finem*." No one understood it, and, in explanation, Duguid said "it was the Abbé de Laborde who spoke, but as he was displaced by another spirit, he could not get a translation." Mr. Black, the veteran artist, said it was "nonsense listening to a French Father speaking in Latin," and rose to go. At this juncture the medium seemed to be wrestling against the spirit who had displaced the Abbé, and, however unwillingly, gave utterance to the following in good English: "I am John Taylor." Here Mr. Urie protested against listening to Taylor, "as he was before the days of carbon printing, and knew nothing of Swan's patent." With much persuasion he was calmed down, so the spirit went on uninterrupted: "I am John Taylor. I know nothing of pigment printing, but something of patents, particularly an alto-relievo patent, for exhibiting specimens of which I had to pay the piper, and as funds are wanted by the committee here met, I ask Mr. Urie to operate on the piper."

This report was given me as genuine, but I suppose your readers must take it *cum grano salis*.—Yours truly,

JO. VANTAM.

DEAR SIR,—Surely a Scotchman can be no longer the "cannie Scot" of old times, or the Glasgow Photographic Society must not be taken as representing the intelligence and shrewdness supposed to be special attributes of our Northern friends. These gentlemen seem to have been holding an indignation meeting lately, and been "going in" against the renewal of Mr. Swan's patent for the manufacture and mode of using carbon tissue. Their secretary, too, has made some amusing researches into the history and modifications of the various Autotype Companies, beginning with Mr. Swan and ending with Messrs. Bird and Sawyer.

Now, if there had been the smallest spark of the national shrewdness amongst these gentlemen, they would, first of all, have made themselves acquainted with the facts—and the facts are these. Before the renewal of a patent is granted, the inventor (and no one else) must declare solemnly that he has received insufficient pecuniary benefit from his invention. Now, as Mr. Swan sold his patent to the Autotype Company for a large sum, it is perfectly impossible for him to do that, and no one else can. Verily these Scotch gentlemen have posed before their brethren in a paradise of ignorance, and their secretary wasted a good deal of time in getting up totally irrelevant matter, when he should have been making himself acquainted with the true state of the case, in order to be able to properly advise his Society. Such a spectacle will be edifying to all, but specially to

NEXSIS.

DEAR SIR,—I am very much puzzled at this time to know what is best to be done. I am desirous of replacing my silver printing by some more permanent method, and had almost decided to become a licensee of the Autotype Company, supposing a license was necessary; but this week I see an advertisement in your journal from a company who are on the point of supplying the tissue and other materials for the working of the process, and I also see that a firm at Barbiton offer to teach me the Lambert-type carbon printing process, and that no license is required.

I think, sir, in the interest of your readers, this matter should be somewhat cleared up.

I see the Autotype Company still advertise their licenses, and this week say that they decline to supply materials except to licensees; but if it be true, as I have been told on very good authority, that the materials can be bought in open market, this move of the Company's is not likely to be of much avail. Altogether, I am in a dead-lock. I think the Company have not been illiberal, and that the price they put upon their license is not ruinous, but nobody likes to pay without the necessity being shown; and if I can get all my instruction, work without a license, and buy my materials in the open market, I, for one, do not see the necessity.

Will you excuse my taking up your space in this matter? Of course, I might have written straight to the Company; but being unknown to them I felt disinclined to do so, and besides, this seems to be a matter that really requires to be explained for the benefit of all your readers.—I remain, yours truly,

J. ELLIOTT.

125, Liverpool Road, Islington, March 26th.

CARBON PROCESS FREE FROM RETICULATION.

DEAR SIR,—I send you a carbon process, perhaps a new one, free from reticulation and many defects, and also without expensive apparatus, such as press, frames, papers, &c. Proceed as follows:—

Coat a hard varnished negative with a stratum of gelatine, formed of

Gelatine	1 ounce
Glycerine	1 "
Water	10 ounces

Allow to dry. Flow with india-rubber solution or collo-dion; then allow to dry. Coat the negative which has a covering of gelatine and india-rubber with gelatinized

pigment solution, and then dry; sensitise in terchromate of potash and alcohol bath, or a mixture of gelatinized pigment, one ounce terchromate of potash or chromic acid, and three ounces of alcohol. Dry in drying box. Place the dried sensitized film on the negative on a piece of velvet, and expose, develop, transfer, and mount as usual.

DEAF AND DUMB ARTIST.

COLOUR OF CARBON PRINTS.

SIR,—It would seem that I had stumbled on to dangerous ground, where "Nemesis" follows fast upon my footsteps. I am disposed to think, however, that the "party" calling herself "Nemesis" is a Bogus article, and not the genuine daughter of Nox. It is as well to be civil, however, even to a pretended deity, and I will, therefore, endeavour to answer the questions which are intended to silence me. I am asked to show cause why the Lambertype licensees ought not to have the monopoly of information referred to, and ought not to preserve it secret, seeing they have made special payment for their licences. This question is intended to be a *poser*. It is, however, easily answered. In the first place, because a patent and secrecy are diametrically opposed to each other, and constitute, in fact, a contradiction in terms. The word patent implies "open," "spreading," as a classical deity ought to know. And the condition under which letters patent become a temporary protection to exclusive rights is, that the invention so protected should be openly described, so that an ordinary workman might put it in operation. I thought it was for the exclusive rights involved in this patent the Lambertype licensees paid. If these really are so shaky that they need to be bolstered up by the aid of secrecy, it is very unwise of those concerned to show it. There is on record at least one similar attempt in the history of photography, and, by odd coincidence, also in connection with carbon. One of the earliest and most enthusiastic carbon experimentalists in this country patented his discoveries, but also kept secret certain parts thereof, endeavouring to gain the cover of two forms of protection incompatible with each other, patent law and secrecy; and his career in this direction was unmitigated failure. I see it announced that one of the licensees, with rare good faith offers to teach all the operations for a consideration, and announces that no licence is required!

Well, I hope I have answered "Nemesis" as to why the Lambertype licensees should not make any claim to exclusive information, as well as exclusive rights to work the patent method. But the Goddess of Vengeance objects that I set up my "dictum as a standard of good taste." That is an error. I never did so. On the other hand, I limited myself to pointing out the fact that Lambertype purple was not a colour selected by artists for their monochromes, but that certain other pigments, easily available to carbon printers, were used by the recognized arbiters of taste. And so far from appearing not to know that pigment of this kind was supplied by the Autotype Company, I recommended it as especially accessible as well as pleasing.

"Nemesis" having attempted to defend the practice of secrecy by Lambertypists, next proceeds to deny its existence, and points out many useful articles in your own pages. Sir, I recognised that fact, and gladly say, all honour to the men who thus distinguish themselves, and maintain those traditions of photography by which its rapid progress has been made certain. Let the most exclusive of those anxious to retain the best methods of permanent printing in few hands remember that had such been the practice of the earlier experimentalists, carbon printing would not have been in its present advanced position.

The Autotype Company, who are now the holders of the Lambert patents, naturally enough wish to offer inducements to obtain fresh licensees, and, as I learn from the letter of "Nemesis," they offer special advantages as to price as well as quality of tissue. This is a commercial bargain, to which no one has a right to object; but the preservation of exclusive information, I venture to affirm, is impolitic, as

well as ungrateful to the earlier teachers. Just at this moment there are rumours and announcements of competition in the manufacture of tissue. Hitherto, the Autotype Company have maintained a reputation for liberal dealing, which is, I should think, worth keeping up. In an open competition their experience and good reputation must stand them in good stead, and help them to secure new as well as old customers. But if their name is associated with the preservation of secrets, and practically in antagonism with the mass of photographers, they then play into the hands of their opponents. In this case, the operation of natural, social, and commercial law will bring about a requital without calling up a Bogus "Nemesis."—Yours,

A CARBON WORKER.

MEDALS.

SIR,—I have read with great interest the letters in the two last issues of the NEWS, respecting the awarding of medals at Photographic Exhibitions. Without doubt it is a matter of much importance to photographers, and I think worthy of more attention than it has hitherto received. No one will deny the value of such inducements to photographers to exhibit: it would tend above all things to elevate the artistic standard of their work: stimulate a healthy competition in the place of the miserable commercial manner in which professional photographers too often conduct their business; and, finally, be a reward to those who by their study produced work which would raise the art in the estimation of all who saw it.

Of course it will be impossible to satisfy all, there are bound to be some heart-burnings at the result of the awards. There seems to be one great bugbear ever present in the minds of our brethren of the "Noble Order of the Bath," with regard to the giving of medals or prizes, and that is the fear of "favouritism" cropping up. Something should be done to remove this fear as much as possible, and I think if those most interested in the matter were to convey their ideas through the NEWS, &c., as to the best manner of doing so, those who have the management of exhibitions, by picking out the really practical suggestions, and adding some of their own, might arrive at a generally satisfactory arrangement, and photographers would then feel more confident that the *best work* will win.

With regard to photographers exhibiting medals bought, or, at any rate, not *won*, by them, I think such doings both mean and contemptible. No man of right principle, or the smallest honour, would stoop to such tricks, and the only consolation others can have is in the fact that it is a *proof* he has no artistic merit of his own, or he would not find it necessary to use other people's laurels in order to induce the public to expend their money, and afterwards their ire, upon him. It is a pity that even such paltry tricks as these cannot be stopped, so that in every case those should obtain

HONOUR TO WHOM HONOUR IS DUE.

Proceedings of Societies.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE usual monthly meeting of this Association was held on Thursday, the 22nd inst., at the Free Library, William Brown Street, the Rev. H. J. PALMER, President, in the chair.

The minutes of the previous meeting were read and passed.

The SECRETARY read a communication from Mr. Ellerbeck, in which that gentleman stated that since he read his paper at the previous meeting he had received from Mr. W. B. Woodbury a packet of his transfer paper, and found it admirable for the removal of negative films from ferrotypes and glass plates. Mr. Woodbury recommended, after the immersion of the film and paper under water, to squeeze the two, and leave them for half-an-hour; then, while still damp, to remove the paper negative. Mr. Ellerbeck found this not possible in the case of metal, the collodion adhering strongly to the iron; but if the whole were thoroughly dried, and, if necessary, heated, a knife passed under

the paper separated the whole at once, and without the slightest difficulty. Care must be taken to have the ferrotype surface clean, otherwise a portion might remain in minute spots, which could only be removed by using ether.

The SECRETARY exhibited several transparencies toned with chloride of palladium. These were considered excellent, and the tone very satisfactory. They had been prepared by a solution of two grains of palladium to one ounce of water; but Mr. Ellerbe thought a weaker solution would do.

The PRESIDENT exhibited some sheets of gelatine made thicker than usual, which he found very suitable for using as substitutes for glass to coat with gelatine emulsion. He (the President) had been using, for the purpose of coating, a simple apparatus which, as they would see, was merely a sheet of tin doubled like a sheet of note paper, the upper half having an opening a little less than the paper or gelatine to be coated, and, being bent a little outward, forming a spring when the two sides were pressed together, and for convenience clipped with the paper between; the emulsion could be easily spread with a glass rod, the paper lying perfectly flat. The tin holder should be slightly warmed before coating with gelatine. He (the President) also exhibited a folding three-sided lamp shade, one side having an opening covered with non-actinic gelatine.

Two portrait negatives of the President were shown, which had been kindly exposed by Messrs. Brown, Barnes, and Co., at one of their studios—one on a collodion plate, and the other on a gelatine plate prepared by the President. The former had an exposure a fourth longer than the gelatine; the result was slightly in favour of the wet collodion plate.

The PRESIDENT then proceeded to give a practical demonstration of Mr. Leach's enlarging process, which was watched by the members with the greatest interest.

The meeting was shortly afterwards adjourned until April.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

A MEETING was held on Wednesday, the 14th inst., Mr. J. J. Leno in the chair.

The minutes of the previous meeting were read and approved, and two new members elected.

The CHAIRMAN having asked if any of the members present could tell him what was the best film for microscopic work, granularity or structure of any kind being what he wanted to get rid of,

Mr. SMITHILLS expressed his opinion that the collodio-bromide emulsion with alkaline development would prove extremely suitable, and would give little texture or granularity.

Mr. ROBERTSON (secretary) then read a communication from Mr. John Urie (see page 147).

The SECRETARY said that after he received Mr. Urie's letter he thought he would take a look at the Autotype Company's advertisements. Although unable to find any Autotype advertisements in 1868, he might not be far wrong if he noted "A Carbon Process on Mica," by M. Despaquis (six sheets for six shillings), and a book by Mr. G. Wharton Simpson on "Photography in Pigments"—a work containing a full account of Swan's carbon process, price seven shillings and sixpence. If the Society or any of the members had a copy of this work he would like to see it. In 1869 the Autotype Printing and Publishing Company, Limited, announced that they were the sole proprietors of Swan's patent for printing in carbon; they granted licenses to use the patent process in consideration of an annual payment of ten pounds, and they cautioned photographers against pretended improvements of the process which were mere colourable infringements, against which it would be the duty of the Company to protect their interests, and those of their licensees. In 1870 the Company gave, gratuitously, practical instruction in carbon printing. The purchase of the apparatus and material included the right to use them without license. In 1870 Mr. J. A. Spencer said he had recently erected machinery for making pigmented gelatine paper as employed in the processes of Poitevin, Fargier, Blair, Pouncy, Edwards, &c. In 1871 the Autotype Fine Art Company, Limited, advertised a sensitive pigment paper; also their new pigment paper. Licensees had the right to use Swan's patent, Johnson and Edwards' patent, instructions being given gratuitously. In 1872 the Company gave a list of their directors, &c. Among these Mr. Spencer's name was found. In 1873 the Autotype Fine Art Company, Limited, announced that the exclusive rights in their patents, together with the factory, works, and plant at Ealing Dene, had been sold to Messrs. Spencer, Sawyer, Bird, and Company, and that they would receive

orders and grant licenses. In 1876 Messrs. Spencer, Sawyer, Bird and Company announced that they had purchased the goodwill and copyrights of the stock-in-trade, and lease of the gallery, late the property of the Autotype Fine Art Company, and their advertisement contained M. Lambert's tissues, presses, and materials for licensees. In 1877 the Company showed a registered trade mark. They dropped the title of Spencer, Sawyer, Bird, and Company, but had the single name of the Autotype Company; and they effected important modifications in the manufacture of pigmented tissues. In January, L. Lambert was announced as having engagements for Canada and the United States, and M. Lambert, jointly with the Autotype Company, would give a reward of £200 to any person who, without using their patents or materials, would produce in the same length of time the different styles of portraiture, permanent and artistic, obtained by the Lambert process. The last advertisement announcing the silver medal award seemed to adopt the name Edinburgh people gave them—the London Autotype Company. He did not know whether these jottings were of any use, but was inclined to think there was some interest and instruction in seeing the changes and development of the Company. He thought it might be said it originated with Mr. Swan, of Newcastle, and after many changes seemed to be the property of two men—viz., Messrs. Bird and Sawyer.

Mr. GILLILLAN said he believed a committee had been formed last year, when the notice of expiry of patent was first pointed out by Mr. Urie, their duties being to correspond with other societies and ascertain their sentiments on this important matter; but the committee had seemingly omitted to take proceedings, and he now proposed that the Society should come to the conclusion to raise objections to the renewal of the patents.

Mr. URIS thought, with Mr. Gillilan, that the movements of the Autotype Co. should be watched, and when it was found they made an application for renewal, objections should be raised.

The CHAIRMAN said it would be better to ascertain the sentiments of other societies before proceeding further.

Mr. JOHNSTON then read a paper on "Organic and Inorganic Matter: their Use in Bromide of Silver Emulsions" (see p. 148).

The SECRETARY then drew attention to a number of photographs (exhibited by Mr. George Mason) by M. Klayr, of Algiers, which would show the members the effects to be obtained by his so-called "improved mode of lighting;" also, some more specimens by Mr. Paton in further development of his imitation of M. Karelne.

Mr. PATON said that at the previous meeting he had stated that in order to prevent his white window curtains from coming out a mere mass of white, he had recourse to colouring them slightly with orange chrome; but he now found that to be wholly unnecessary, as, by putting the dark background which formed the sides of the window, they were easily photographed so as to come out quite distinctly.

Mr. GEORGE MASON pointed out that Mr. Urie was of opinion that the patent the renewal of which was under discussion was not a valid one, and the Autotype Company, according to his statements, could do him no harm if he persisted in working in carbon, despite the Company; and if such were the case, why should the Society be asked to fight against nothing? Those who were not patentees, and wished to work in carbon, but objected to paying any royalty, and were as confident as Mr. Urie that they could not be restricted, should at once set to work with the process in defiance of the Autotype Company.

Mr. URIS replied that, though not fearing the result, the mode of procedure referred to would likely cause any artist, personally, a considerable deal of trouble, and possibly expense, and therefore thought the course he advocated—viz., the formation of a committee, and the appeal to kindred societies for help and support—the better plan.

Mr. DONDS stated that Mr. J. A. Spencer, late of the Autotype Company, had himself, before he became a partner, held that the patents were not valid, and no restrictions could be placed on his working the carbon process, which he had proved by practising it for a considerable time in spite of the Autotype Company's attempts to stop him.

Mr. MASON said Swan's patent—the one under discussion—was a single transfer process, and could not harm those who were Lambert's patentees, seeing theirs was the double transfer.

Messrs. URIS and DONDS declared that both single and double transfer were included in Swan's patent, the only thing (Mr. Urie further pointed out) being that Swan did not claim the use of unsensitized paper or tissue in his provisional specification, his

mode of working it being the pouring of the collodion and carbon on a sheet of glass, and stripping the film off, ready sensitized.

Mr. GILFILLAN moved that a new committee be appointed to oppose any application for the renewal of Swan's patent by the Autotype Company, and to confer with other societies in order to elicit their sentiments and secure their co-operation.

The motion having been seconded by Mr. McPherson, Messrs. Bowman, White, Urie, Smart, Bell, and the Secretary were appointed.

The Chairman said he believed the idea was a good one, and could see, with Mr. Urie, that carbon printing would receive a great impetus, and its advancement be materially affected, if the patent rights could be got rid of.

Mr. Mason drew attention to the somewhat anomalous conduct of the gentlemen who were advocating resistance to the renewal of patent rights to the Autotype Company, in so far as for many years they were quite at liberty to work the carbon process, if they chose, without paying any royalty; but seemingly none, or at least very few, of them availed themselves of the liberty. To them it existed as a scientific fact alone, as of commercial value it was nowhere; but immediately Mr. Lambert appeared, and, by paying a royalty or buying the right, a few of their neighbours got an advantage over them, they seemed to be suddenly awakened to the fact that as a commercial speculation the carbon process was likely to prove a success, and longed for the liberty they once had, but thought right if until it was taken from them.

The Secretary stated that he could not see what M. Lambert had to give in return for £30.

Mr. Paton said that, after having seen M. Lambert work, and the exceedingly beautiful results obtained by the process, he had bought up the right for his particular district. Unlike his other patent purchases, this one had proved a commercial success, although he had previously known nothing at all of carbon printing. M. Lambert had enabled photographers, by his improvements and modifications, to produce small carte work in carbon, which before was almost exclusively used for work of a large size. He believed there were some men here and there working the carbon process without paying for a licence, but those had got the liberty from the Autotype Company before M. Lambert had come to the front, but still the materials those gentlemen obtained were not at all to be compared for excellence with what he (Mr. Paton) got, and, further, small work was beyond them. He felt quite satisfied with his purchase, and considered he had got an adequate return for his money.

Mr. Mason also explained that Lambertaines were altogether different things from the usual productions of the Autotype Company, and that those gentlemen of whom Mr. Paton spoke had been workers in it for many years, having, when they first purchased their materials from the Autotype Company, obtained the right, the Company at that time granting the liberty to those who purchased the materials from them.

Mr. Urie stated positively that he had produced pictures in carbon fifteen or twenty years ago, and could do so again. He had placed on the table, last season, pictures quite equal to those now produced by Mr. Paton, although he had never seen the Lambertaine process worked; and now, because he had not purchased his materials from the Autotype Company, and objected to paying the holders of Lambert's rights the sum demanded, he was debarred from using the process or improved materials. Mr. Paton had stated that he did not know anything about carbon printing until instructed by M. Lambert, for which lessons he paid a considerable sum. But what was he (Mr. Urie) to get in return for his money when he knew all about the process already? Was it only that better materials would be supplied by the Company? They were not asking to work Lambert's patent. All they wanted was to prevent the renewal of an old patent that had run its legal term of fourteen years.

A vote of thanks to the Chairman, closed the meeting.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next meeting of this Society will take place on Tuesday evening, April 3rd, instead of the usual second Tuesday in the month, at eight o'clock, at the Gallery, 52, Pall Mall East, when the adjourned discussion on the "Silver Bath," opened at the March meeting by Mr. John Spiller, F.C.S., will be resumed.

TRADE CATALOGUE.—Mr. R. C. Thomas has just issued a new catalogue of photographic chemicals and other appliances for the photographer, which he has in stock. It is an amazingly complete repertory of photographic requisites, which we commend to the attention of our readers.

CRUICKSHANK IN SPAIN.—An interesting paper was recently read by Mr. S. Flint (Clarkson), at the Architectural Association, based on the photographs taken by Mr. J. C. Steuning and Mr. John MacAndrew, of early churches in the Asturias.

To Correspondents.

IRON.—The most common cause of similar streaks, in our experience, is the formation of a surface scum on the bath, which should be carefully removed by drawing strips of clean blotting-paper over the surface before immersing a plate. In some cases streaks may be prevented by keeping the plate in lateral motion whilst it is in the bath.

T. B. R.—Judging from your statement and the piece of stained paper you enclose, you have not read or understood the instructions for working the carbon process. The dark side of the tissue must, of course, be placed in contact with the face of the negative, and then the same dark side be placed in contact with the glass or transfer paper, whichever you use for developing on. Carefully read the instructions given in many articles in our columns, or obtain the Manual of the Autotype Company, and follow the instructions.

NIL DESPERANDUM.—There are no definite rules of the trade yet established. It is too young a trade to have any definite or recognised laws in such matters. All such matters are generally subjects of special agreement, and where no agreement exists the master generally decides on his own judgment, or convenience, or estimate of fair play. An observant apprentice may constantly be learning something, in whichever department he may be employed, but one year in the operating department to six in the printing department gives certainly some excess to the latter.

J. W.—Make a 32-grain bath with pure distilled water for negatives; a 60-grain bath made with tap water for prints. Proceed much in the same way as in producing collodion positives, giving, however, a little longer exposure, and continuing the development much longer. Sensitive paper may be kept in good condition some time if placed between sheets of blotting-paper which have been immersed in a solution of carbonate of soda and dried, as described several times in our pages. The toning bath, if carefully kept from contact with dirty fingers, or other causes of contamination, may be used over and over for many batches of prints, but fresh hypo must always be used for each batch.

WELLINGTON.—It is not difficult to estimate the cost of the material used in producing a dozen card pictures, but it is more difficult to estimate the value of the artistic skill and training employed in producing them. When a man puts very low in price, it is evident that he estimates the value of his time and skill at a very low rate, and an artist who respects himself and his profession will not enter into competition with him. Do not be induced to enter into a race for the lowest price, rather aim to produce superior work.

A. P.—You will doubtless find that the Autotype Company, who are owners of the patents, hold a very different opinion as to the necessity of a licence for working the Lambertaine process, an opinion they will probably enforce in Court. Unless you wish to test the question by becoming defendant in a chancery suit, we should not advise the risk. See some remarks in a leader in this number.

G. WRIGHT.—We will endeavour to ascertain. We think it very doubtful that any conditions would be agreed to at the time of enlistment, and in any case a certain time—several months, we believe—must be expended in drill and training.

RESIN IN ALCOHOL.—A large number of the gum resins are soluble in alcohol. Shellac, mastic, sandarac, and various others are soluble, wholly or in part, in alcohol.

Several Correspondents in our next.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHY IN THE LAW COURTS—INDIA-RUBBER AND ITS DEGREE OF SOLUBILITY—A GOVERNMENT ASTRONOMICAL OBSERVATORY IN FRANCE.

Photography in the Law Courts.—Photography has often given evidence in a court of law, but it is rare to make use of illustrations produced by the art in the manner adopted in a civil action lately. A tradesman sought to recover damages on behalf of himself and his family on account of being poisoned by American tinned meat. It was alleged that having partaken of a tin of some preserved animal food the family were at once stricken with sickness, and the sufferings undergone, and doctor's expenses incurred, formed the basis of an action against the merchant from whom the tinned meat had been purchased. The latter indignantly denied the circumstance that anybody could be taken ill from eating the meat he imported; on the contrary, he was prepared to show that those who continually fed upon such provisions were unusually well and healthy; and his learned counsel, to make good the assertion, presented the jury with photographic portraits of the defendant's family, which had been brought up mainly upon the food in question. The pictures presented the boys and girls in question of a singularly rubicund character, all of them full-faced and round-cheeked. Such evidence seems at once to have convinced the jury, for they soon afterwards returned a verdict in favour of the defendant. We suppose the time was limited, or otherwise the course of the plaintiff was clear under the circumstances. He had nothing to do but rebut the evidence adduced by the defendant. Against the rubicund family series of the defendant—the portraits, no doubt, cunningly retouched to dissipate any wrinkles or folds in the skin, and make the sitters appear as sleek and fat as possible—the ill-used plaintiff should have set another series representing his family, ill and emaciated, as they no doubt were. With judicious lighting and exposure, very suitable pictures for the purpose might easily have been secured, and these would, no doubt, have told upon the jury with quite as much weight as did the rival pictures of the tinned meat merchant. If photography is to be employed on one side, it is only fair that it should be represented on the other. The defendant had evidently stolen a march upon the plaintiff, however, and taken him unawares. It is singular that the plaintiff did not guess the defendant's line of action, for the idea was not a new one, although its application may be. Mr. Wackford Squeers, as everybody knows, always presented his well-fed boy as a proof of the highly nutritive food dispensed at Dotheboys Hall, and we have no doubt whatever that had cartes-de-visite been invented in his day, Mr. Squeers's pocket-book would have been full of them.

India-rubber, and its Degree of Solubility.—Photographers are well aware of the difficulty with which some samples of india-rubber dissolve in benzole, even when the former has been masticated with great care—and, indeed, this circumstance has stood in the way of its application in photographic processes frequently. Sometimes it has been affirmed in these columns that rubber will easily dissolve, while at other times complaints of the impossibility of getting anything but a thin solution on the application of benzole have been rife. The reason for this appears to be that rubber from various countries differs very greatly in its solubility, and a German chemist, Heeren, has shown that benzole will take up in solution four times as much of one rubber than of another. This chemist has made a careful examination into the solubility of a dozen different species of rubber, and having first worked the samples between hot rollers to masticate them, he cut them into thin strips, and added benzole. After frequent shaking, and securing solutions of as thick a consistence

as possible, it was ascertained how much in a certain volume of liquid there was of india-rubber. Guajaquil rubber was found to be the most soluble, one hundred parts of benzole taking up as much as twenty-five parts of this description of caoutchouc. Next came Para, of which one hundred parts of benzole took up twenty of rubber, and this was followed in solubility by Carthagena and Borneo samples. The worst examples, so far as solubility is concerned, were so-called Africa—Knakels, Africa—Niggara, and Madagascar. This last was very difficult indeed of solution, one hundred parts of benzole only taking up six parts of the rubber—a fact that may afford some consolation to photographers who have been trying their hardest to get a sample of caoutchouc to dissolve. We do not know much about Guajaquil rubber, which stands at the head of all the samples examined by M. Heeren, but Para rubber, which stands second, is always to be had in the market, and in this country enjoys a reputation for being the best article. Very little rubber is, however, soluble before being masticated, photographers should remember, and those who employ it, either in the form of a preliminary coating or in the preparation of films, should bear in mind that a vast amount of trouble and labour may be avoided by purchasing the material already masticated. It is to be bought in the form of thin sheets, something resembling tripe in appearance, and in this worked condition it will be found very soluble in benzole. Some photographers, we know, purchase india-rubber cement, which is but rubber dissolved in benzole, and this they dilute with more liquid till of the required consistence; but this cement, unless very pure and of exceptionally good quality, is not adapted to photographic manipulation. It contains a large amount of foreign matter from dirty rubber or from impure benzole spirit, and this, so soon as the cement is diluted, appears most unmistakably upon the film in the form of black particles and coarse fibre. The best plan, therefore, unless the solution is simply required as a cementing material, is to purchase the finest rubber in a masticated form, and, after washing it in hot water and drying, to dissolve the same in the best sample of benzole that can be obtained. Some advise the previous softening of the material in chloroform, but this we have never found to be necessary if good soluble rubber is at hand.

A Government Astronomical Observatory in France.—The French government have resolved to make good use of the old Chateau de Meudon. This favourite picnic resort, surrounded by a fine park and woods, shared the fate of St. Cloud and many other grand dwellings in the neighbourhood of Paris, being burnt during the last war. The four walls only are now standing, and the French government has decided to have the building restored as an astronomical observatory. The height of the grounds naturally recommends it as a site for such an establishment, and, as our Paris Correspondent has already informed our readers, M. Janssen, the well-known astronomer, has been named director of the new institution. No one will grudge M. Janssen his good fortune. He has worked long and arduously in the cause of science, and has undertaken several tedious and dangerous journeys on behalf of the French government and scientific bodies. His last pilgrimage was to Japan, when he headed the French expedition to that country to undertake observations connected with the transit of Venus. The hats and tents that were carried on this expedition were all carefully brought back with the instruments, and the French government having permitted the farther use of them by M. Janssen, that gentleman did not delay their erection again outside Paris on Buttes Montmartre, where he continued his interesting researches with telescope and camera. A permanent astronomical laboratory has now been sanctioned, as we have intimated, at the Chateau de Meudon, and thither M. Janssen has now removed his impediments until a permanent building shall have been got ready to receive them.

PREPARATION OF EMULSION PLATES BY DAYLIGHT.

BY DR. OSWALD LOHSE.*

POITEVIN described, as far back as 1863, a photographic method which provided for the greater part of the preparation of sensitive plates outside the dark room, and in the midst of open daylight. The method was based upon the property of iodide of potassium, not only to render iodide of silver non-sensitive to light, but to annul any action of the light which had taken place, so that on the application of an ordinary developer no result was to be obtained. The sensitizing of the plates was undertaken with tannin.

The employment of this process of Poitevin appears to have been very limited, and at the present day an operator would not, without much pressing, leave his dark recess to go into full daylight to dip the collodionized plate into the bath. How is it possible to annul this extraordinary action of the light, when it often gives us the utmost trouble to prevent a fogging of the picture, owing to a slight defect in the dark slide, or from the penetration of rays through a chink in the door of the dark room. Is not the quantity of light which the lens admits, and by the aid of which the deepest blacks in the negative are produced, so very small in comparison with the flood of light which comes direct upon the plate in daylight, to say nothing of sunlight? And yet in the Poitevin method there was nothing to fear from the action of such powerful rays. The treatment with iodide of potassium which followed the washing of the plate destroys all results of the action of light; even a slight blackish-browning of the iodide of silver has no influence upon the negative to be subsequently produced.

It is not necessary to point to the advantages which a process enjoys, the greater portion of which is to be carried out in full daylight. As to the sensitiveness of the iodide of silver films after their treatment with iodide of potassium, and afterwards, in the dark, with tannin, I have not, I will admit, arrived at particularly favourable results, as the great advantages which the method in question has for my photo-astronomical work has caused me to essay other substances besides tannin, albumen in combination with ammonia being one of them. By means of these substances I succeeded in securing a sensitiveness which for the reproduction of well-lit landscapes was quite satisfactory. Having so far been successful, I next proceeded to find out whether I could not, beyond the advantage of working in the daylight, also do away with the silver bath, or, in other words, I desired to find out whether I could not apply the de-sensitizing action of the iodide of silver solution to the bromide of silver emulsion process. I was met at the commencement with many difficulties, for I experienced considerable trouble in securing pictures perfectly free from fog. I developed with pyrogallie acid and silver, and, as soon as the latter was added, I became at once aware of the fog in the dark room. Dipped plates and emulsion plates treated alike were very different in their action; while the former gave perfectly clear pictures, the others invariably fogged.

It would lead me too far were I to make known the many experiments—some of them of practical importance, no doubt—which I undertook to get at the source of this error. The phenomenon became all the more mysterious the more searching were my investigations. Finally, however, my efforts were crowned with success, for I found that the fog sensibly diminished when an alcoholic iodide of potassium was made use of. This at once enlightened me. The emulsion plates were washed in the same way in the rinsing water, and then treated with a five per cent. solution of iodide of potassium. By washing, the pores of the collodion became closer, the iodide of potassium solution could not completely penetrate, and, consequently, was

unable to annul the action of the light. The emulsion plates prepared in daylight were, before even the ether and alcohol had altogether evaporated, dipped at once into an alcoholic solution of iodide of potassium, and in this way I secured clear negatives, full of detail. To set out a more intelligible statement of my present mode of preparing my plates, I have drawn up the following details of the process.

Manipulation.—The glass plates upon which the collodion is to be poured are, in the first place, washed with water, and then dried with a linen cloth. Then a broad camel-hair brush is drawn across the surface to remove any dust or fibres. A dilute solution of caoutchouc in benzole is poured over the plate, and the latter put on one side to dry. After a few minutes the emulsion, whose composition I give below, is poured on with care, and very slowly, the collodion being permitted to flow backwards before it runs off. When the emulsion has set, the plate is forthwith put into the alcoholic solution of iodide of potassium, which has previously been acidified with acetic acid. In this solution the plate remains for some time, until the oiliness upon its surface has disappeared; it is then washed in the dark, and poured over three or four times with albuminate of silver, rinsed, and exposed wet or dry. The development and intensifying with pyrogallie acid and citrate of silver are best done in a porcelain dish, as well as the fixing.

Description of the Preparations Employed.—The emulsion is prepared in daylight, in the well-known manner according to the following formula:—

Normal papyroxyl collodion of four per cent. strength	...	35 cub. cent.
Normal collodion from gelatinized cotton	...	25 "
Ether	...	16 "
Alcohol	...	24 "
Bromide of cadmium	...	1 gramme
Nitrate of silver	...	1 "

Shortly after the mixing of the constituents the bromide of silver appears of a curd-like consistence, but after the lapse of six to eight hours a serviceable emulsion is formed. Washed emulsion, which can also be produced by daylight, is likewise suitable for the purpose. If it is desired to allow the emulsion to remain in a light room for some time, it is well that it should be preserved in a bottle of yellow glass, or the vessel covered with a paper envelope. Instead of bromide of silver, chloride of silver may also be employed as emulsion. I then work according to the following formula:—

Collodion	...	as above
Chloride of calcium	...	1 gramme
Nitrate of silver	...	2 grammes

This emulsion is somewhat less sensitive, but is to be recommended when a picture of a well-lighted landscape is desired in which the sky is not solarized.

De-sensitizing Fluid.—The alcoholic solution of iodide of potassium, with which the plates are treated after the emulsion has set, brings about a superficial change of the bromide or chloride of silver into iodide, a transformation that is apparent by the yellow colouring to be observed. In the bromide of silver emulsion there is both iodide and bromide of silver in the film exposed, and then there should be more sensitiveness than in the case of employing the silver compounds separately.

As bromide of potassium solution also acts as a de-sensitizer, and possesses the property of transforming chloride of silver into bromide of silver, we have in our hands the means of preparing many combinations of mixtures of chloride, bromide, and iodide of silver to be employed as sensitive films, which would be useful for various purposes.

As regards the amount of iodide of potassium in the de-sensitizing liquid, this is a matter of more or less impor-

* Photographisches Archiv.

tance only. I employ as nearly as possible the under-mentioned mixture :

Water	45 cub. cents.
Absolute alcohol	45 "
Acetic acid	10 "
Iodide of potassium	5 grammes

From time to time, some new iodide of potassium is added. The solution becomes of a yellowish red on the addition of acetic acid.

Sensitizing Liquids.

No. 1.—Albumen...	67 cub. cents.
Water	33 "
Ammonia	12 drops
No. 2.—Nitrate of silver...	6.25 grammes
Distilled water	100 cub. cents.

And as much ammonia as is necessary to make disappear the precipitate formed on mixing.

On employment, a quantity of No. 1 sufficient to cover a plate is poured out in the dark, and to it is added a few drops of No. 2.

Instead of albumen, other substances may be employed with advantage; as, for instance, flour, starch, gelatine, ordinary glue, gum-arabic, caragheen moss, milk, &c.

Developer and Intensifier.—The ordinary formula for preparing pyrogallie and citric acid silver solutions may be here employed.

By means of the process which I have described, I have secured very clear and detailed landscape pictures, and can recommend the method to all photographers to practise upon and perfect who are interested in the technical elaboration of the art, and who wish to emancipate themselves from many of the complicated, and in some cases faulty, manipulations to which we have been clinging for some time past.

M. LAMBERT'S INSTRUCTIONS FOR CARBON PRINTING.*

"In developing, do not pull the tissue too hard, and not up, but down, or let it come off by itself in the vertical trough. A glass which has already been used once in the process must not be washed or cleaned again; simply scrape the collodion from the edges, then wax, &c. It is advisable to put the glass, after laying on it the pieces of tissue, under pressure for about a quarter of an hour previous to development. Should your prints, when finished, have little glossy spots, it is a proof you have put your transfer paper in water too hot or too cold, or have kept it for too short or too long a time in the warm water; you must use water just warm enough, and leave the paper in just long enough to feel slimy. You can avoid all these glossy spots by immersing the transfer paper in a very warm weak solution of white gelatine filtered, previous to applying on the glass. All these glossy spots are caused by non-adherence of transfer paper on film. If you wish a matt surface, develop on the ground side of the plate; if you wish the albumen paper glossy, mount the prints as usual, and roll them. Always develop a little more than apparently required. Never develop too quickly, as if you use water too hot the film will take a wrinkled appearance, as of myriads of little broken lines. After fixing with alum, to harden the film, wash well. Never use a glass to develop on unless its edges have been well roughened on grindstones, or it will cut the collodion, which will run off in developing. If you leave the pieces of tissue too long in the water before applying to the glass to develop, they will curl up, and may not stick to the glass. If you put the collodionised glass in the water before it is well wet, the collodion might leave the plate after and form spots. Better leave your collodionised plate in the water too long than too short a time.

* Continued from page 57.

"Never hurry the drying of the prints after development, for the film will then break and fly off. Before placing the pieces of tissue on the glass for development, place them in cold water until they get flat, and always throw a little water on the glass before applying them on it. Apply the pieces of tissue on the glass by placing at first the lower end on the glass, and lowering the top end gradually, so as to drive away all air-bubbles. If the tissue is properly placed it will move easily on the glass; if not properly placed, you can repeat the operation.

"Thin your collodion if too thick to collodionize your glasses, to develop on, with half ether and half alcohol. As soon as the pieces of tissue touch the water they lose their sensitiveness, so you can develop in full light. Never use a jet of hot water to reduce a print, as often done, because you destroy half-tones (unless the print is too much exposed and you have not time to print another). It is advisable to use the water not too hot to begin with, and to heat it gradually.

"Never use zinc to develop on; ground-glass is preferable, as it gives more softness and half tones. Never print in the sun; if so, print until the photometer shows a quarter more exposure than would be required in diffused light.

"Always cut the pieces of tissue a little smaller than the negative you wish to print from.

"Should you not have light enough to quite finish the exposures, develop the next day, as there is continuation of insolubility even in darkness.

"In damp weather the tissue is more sensitive, so exposures less. A vigorous negative will, with the same tissue, produce a warmer tone than a weak one.

"Put the transfer paper in very clean water, warm enough to make it slimy and sticky, or there will be no adherence, which would produce innumerable very small air-bubbles. After the application of the transfer paper, you may dry by heat or by the sun. Never transfer before the prints are completely dried. The transfer paper must always be cut a little smaller than the glass it is to be applied to. If your water is either too hot or too cold, there will be glossy spots on your prints. A few drops of ammonia in the warm water in which to immerse your transfer paper will prevent the glossy spots on prints which are caused by non-adherence; the ammonia renders the gelatine more soluble.

"After floating the transfer paper on the warm water, and rubbing the face of it with a fine sponge, to take off air-bubbles, dust, &c., apply it on the glass as explained for the pieces of tissue. Touch the water also with the glass (provisional support), face downwards, before applying the transfer paper on it.

"If the film has a tendency to peel off in drying, before transferring, you can avoid it by rubbing off the wax from the edges of the glass (before collodionizing) with a cloth and a little alcohol. When the transferred print is dry, cut the edges off and pull it away.

"For full-enamelled prints, which you wish to mount on cardboard, rub the wax off from the edges of the glass so that the cardboard sticks well on it. Use the cardboard a little damp by placing it between damp sheets of blotting-paper.

"If you wish to mount your prints full gloss, this is the best way. When the transfer paper on prints is about half dry, apply, with starch or paste, a thin cardboard, previously placed between damp blotting-paper; when very dry, pull it off from the glass, cut the prints, put glue on the four borders, and mount on your own cards, taking care not to wet the face of the prints. The longer the prints are left on the glass, the finer will be the gloss.

"In commercial work, when the transfer paper put on prints is quite dry, put it in water for a few moments, pull off then from the glass, and mount the same as for silver prints.

"If you wish to mount full gloss prints on very thick cardboard, do as follows:—Rub starch paste on both the

transfer paper and cardboard, and stick them together while yet on the glass; then put under pressure for half an hour, and let dry.

"Wax your ground-glass as follows:—Coat with waxing solution, rub once or twice only with papier Joseph, then polish well immediately with flannel. Mount them as you would an albumen print on your usual cards; spot, roll, and encanticate them. Develop on ground-glass, waxed and collodionized. Mount while yet on glass, as for full enamel prints.

"Always border your negatives or transparencies before printing from them; for if not bordered with black paper as taught in demonstrations, the film printed from either of them might wash off during the development, or the edges or other parts of the film might curl, crack, or peel off.

"You might lose half-tones in high-lights if you use old sensitized paper, or a sensitizing bath too old, or used to sensitize too much paper.

"Always use clean water to put your glasses in after collodionizing.

"For prints developed on ground-glass, without collodion, you can obtain the double albumen paper gloss by rolling with a hot press, and waxing the prints while yet warm.

"A full enamelled print will be about one-third stronger when dry than while yet on the glass.

"If you wish to colour a finished chromotype, rub its surface with alcohol previously.

"If you have to retouch a white spot on the light parts of the print when yet on the glass, do so with indian-ink, to which add other colours to get the tone desired, and spot as you would an albumen print; then take a little collodion on your brush, and let a drop fall over the retouching to imprison it, and when dry, transfer. To retouch on tissue while yet on glass, use a very soft pencil, wetting the point of it often. It will stand water.

"If there is any wrinkling or reticulation on the prints or transparencies, it is caused by the paper being dried in a room which is too hot. Should the print stick to the glass by bad waxing, you may save the print or clean your glass by putting it to soak in water. If the print comes out entire, you can mount it like an albumen print.

"If you wish to reintensify transparencies a black-blue tone, use,—

"Solution No. 1.—Warm water ...	4 pints
Gallio acid ...	60 grammes
"Solution No. 2.—Sulphate of iron ...	40 "
Acetic acid ...	40 "
Water... ..	2 pints.

"Mix in small quantities, and use to reinforce either negatives or positives."

THE OFFICE OF VIOLET RAYS IN THE PRODUCTION OF NEGATIVES.

BY LEON VIDAL.*

FOR some months past, thanks to M. Scottelari, the question of lighting studios by means of violet glass has once again been discussed, and, in entertaining the subject, photographers have occupied themselves much more over the greater rapidity of such a method of lighting, than of all the other advantages which it leads to. Practical experience is certainly the best guide in matters of this kind, and no theory, however subtle it may be, should be preferred to it.

Experiments upon the action of violet rays projected upon objects to be reproduced in the camera have already been made under various auspices, and it will be prudent, before forming a conclusion that shall be safe from attack to await the verdict of those who have undertaken such experiments. Our object is not to affirm anything in

advance, but only to support the research now being made by a few observations and speculations.

Nobody occupies himself with photography without knowing that the violet rays of the solar spectrum are those which are endowed with the greatest chemical activity; but what is not generally known is the quantitative relation existing between the visible and invisible rays of the spectrum, and also the actinic power of the invisible rays situated upon the spectrum band beyond the ultra-violet. In order to be perfectly understood by those who are not initiated in the mysteries of the decomposition of light by means of a prism, it will be well for us to explain what is understood by invisible rays, and how it is possible to know of their existence.

A pencil of solar light being projected upon a prism, its decomposition is at once brought about, and the different rays of the various rays unequally refracted form upon the surface of a screen placed in their path a rectangular and polychromatic band which is termed the solar spectrum. The screen upon which the spectrum is projected may be the ground glass of a camera of which the lens has been taken out to make way for a prism.

To the eye the coloured band is clearly perceptible, and it is easy to trace, by means of a pencil, the limit on one side of the violet rays, and that of the red rays on the other.

If the limit of the violet rays is led, first of all, to the right of the ground glass, nothing but complete obscurity is to be observed upon the surface. By substituting, however, a sensitized collodion plate for the ground glass, and securing an image by development in the ordinary manner, there will appear upon the film a black band, almost as long as that of the visible spectrum, and representing a prolongation to the left of this. This prolongation is due to the invisible rays which are a continuation of the violet rays, and whose actinic intensity diminishes until they meet or fuse into the red rays, supposing the band of the spectrum to be annular.

Thus it is seen that between them the invisible rays and the visible violet rays possess an actinic power at least equal, if not superior, to the whole of the other visible rays; and if we add the very actinic action also of the blues, there remains but to take into consideration the inactive yellow and the two colours dependant upon it, the green on one side and the orange on the other, and finally the red.

Now, violet glass permits the passage of the invisible rays and of the violet and the blue, and the polychromatic object to be reproduced, therefore, is bathed in a light of an essentially actinic character. Moreover, the red colour combined with violet rays loses its lack of actinism, and is reflected not only in the condition of a red colour, but in that of a carmine. It impresses the iodide of silver just in the same way as rays of the last-mentioned colour do when white light is reflected on it; that is to say, under the circumstances of violet illumination you are certain to obtain very nearly the effect of the red with an exposure sufficient for the violet and blue rays to act.

Yellow and its combinations are yet tardy in their action, yet not to that extent as when they reflect only white light, because one has the benefit of the greater actinism produced by the combination of this colour with violet rays.

The above are the arguments which lead to an *a priori* reasoning that violet illumination will shorten exposures; and it is for this reason that we believe in the efficacy of violet light projected upon a polychrome object to be reproduced, being of opinion that under the circumstances more perfect negatives would be obtained in respect to the relative value of the colours upon the model. Not that the important question of relative value is thereby definitely settled, but that we are now one step nearer its solution. We ourselves shall take an opportunity of returning once more to this subject at an early moment, when the results of some important essays which we are making in the matter shall have been secured.

* *Moniteur de la Photographie.*

HOW TO PRODUCE FAULTLESS PICTURES FROM DEFECTIVE CARBON TISSUE.

BY H. NORDEN.*

It has happened to many who have busied themselves during the past summer with carbon printing, that they have met with difficulties in regard to the tissue, and been so plagued with unsuccessful results, that they have lost all desire and courage to work the process. I have succeeded, by having recourse to a simple plan, in annulling the worst of all defects in carbon printing, and have been able to produce good impressions from even faulty tissue.

During the past summer, when many carbon printers after continued insuccess and vexatious failures, turned their attention once more to silver as a medium for their pictures, I have been able, by the aid of the method to which I refer, to continue to print in permanent pigments surely and uninterruptedly. That the faults are due to the tissue alone rests upon an incontrovertible fact, which I will communicate in a few words.

It was in May last when I first made the acquaintance of these very unamiable qualities of the carbon tissue. The events coincided exactly with the opening of my newly-erected studio for carbon printing, and my vexation and injury were the greater, as I was in this way rendered powerless to supply the carbon prints which I had promised. I tested all sorts of carbon tissue from various manufactories, and with always the same result: there were grain and reticulation to be seen always after development, which not only injured the tone of the picture, but robbed it of all its delicacy and beauty.

In my experiments, which went so far as the examination of samples in my waste paper basket, testing old cuttings and remnants of tissue of a previous date, I discovered a large piece of tissue which, under exactly the same circumstances, yielded me quite faultless results. By a closer examination of this paper, I found that the tissue in question contained no soap, while all the other tissues, as soon as they came into the warm water, at once spread a black kitchen atmosphere, while the water on being much agitated gave a froth similar to that seen upon a washing tub.

Further experiments which I made in the preparation of carbon tissue confirmed my first suspicion that soap was the base enemy in the tissue which, in summer time, brought about those phenomena which are the despair of all carbon printers. A closer research into the matter which I made need not be here described in detail, as it would lead me too far, and at the same time scarcely interest the readers of these lines; suffice it to say that I found, when soap was present, that the ugly phenomena occurred, which were not to be met with when this compound was not a constituent of the tissue. Thus it was absolutely proved that the fault was in the tissue itself.

I will now briefly communicate in what manner I am able to eliminate from tissue the defects it presents on development, whether these consist in a reticulated or grainy film, or in tiny bubbles in the case of development on glass or transfer paper, or in a loose attachment to the basis on which it is developed.

I sensitize in a four per cent. chromate bath, putting in the tissue in the rolled-up form in which I buy it, the material being gently and slowly passed into the bath and unrolled from the top. (This method has, however, nothing to do with the removal of failures, and I only communicate it so that others may know my precise method of working). As soon as the tissue stretches itself out—not longer—I take the sheet out with as much liquid as possible, and place it, avoiding air-bubbles, upon a patent plate that has previously been covered with a five per cent. solution of oxgall; the sheet of tissue is then squeezed, and allowed to dry on the glass. After printing in the ordinary manner, the tissue is immersed in water, and here placed upon a waxed and collodionized plate in the manner following

* *Photographische Artiste.*

I take the sheet, which, by reason of its drying upon glass, is very smooth and even, and holding it vertically with the lower edge in the water, lower the tissue till it touches the bottom of the bath. By continually pressing downwards and forcing the film away from oneself, the whole sheet is brought under water, the operation being facilitated by adding a wavy motion to the sheet. The operation must be performed quietly, and without any hesitation. As soon as the tissue is under water, I wait a few seconds, and before the tissue has well time to stretch itself, I take it, lying in its proper place on the glass, out of the bath and squeeze it, putting it back again, pressed as it is into the water, until I am ready to develop. I have permitted pictures to remain for hours in water in this way without having observed any material change one way or the other in them. In any case, however, it is indispensable, if you wish your picture to develop perfectly, to let it remain for ten to fifteen minutes in the cold water, so that it may be quite saturated.

As soon as this is the case, I put the glass plate into the dish of pretty warm water, from 35° to 40° Reaumur, in which case the paper backing is soon removed. As soon as this happens I put the glass plate into a developing dish with a trough bottom (taking care to avoid air-bubbles), the image being placed face downwards. In this developing dish the water is not more than 23° R., and the image is allowed to develop by itself.

After development, I rinse with warm water, and afterwards with cold, put the plate for a few minutes in alum solution, rinse again, and put it to dry.

In the case of tissues which possess the above-mentioned defects only in a slight degree, this manner of treatment will suffice to yield good pictures; but in the case of very bad tissue there is still one other manipulation necessary, the performance of which, however, is amply compensated for by the production of brilliant and certain results.

The handling of such tissue remains exactly the same up to the end of the printing process. As soon as a sufficient number of printed carbon sheets are at hand, I proceed in the manner following:—Collodion which has served for

the coating of the waxed plates is diluted with four-fifths of its volume of alcohol; this is poured into a metal dish, the size of which must be governed by that of the picture. The length of my dish is that of a cabinet picture. For larger pictures I have another mode of proceeding, respecting which I may, perhaps, have a subsequent opportunity of speaking. I now take the printed pieces of tissue, draw them well through the diluted collodion, and hang them to dry by means of American clips, the drying being complete in from ten to fifteen minutes, according to the temperature of the atmosphere.

After drying, the treatment of the tissue is precisely the same as that above described, and photographers will find that not a single case of defective development will come under their notice, even with the worst kinds of tissue, if they follow this plan of working.

The retouching of carbon prints may be undertaken with ordinary gum or albumen colours, the developed picture, after it is dry, being once more coated with thin collodion. If this is not done, then, notwithstanding the perfect appearance of the picture upon the glass, the disagreeable network formation will appear again as soon as the image is transferred to paper, and your labour and trouble will have been in vain.

Those who have not to struggle with tiny air-bubbles on transferring upon glass, need not let the tissue, after sensitizing, dry upon the glass plate, but have only to remove the superfluous liquid by pressing with a glass rod to the right and to the left, and to hang up the tissue to dry.

RAPID CARBON PRINTING.

WE are favoured by Mr. Witcomb, of Salisbury, with another communication on what is termed by the Lambertype licensees "chromotype" printing, together with two charming card-portraits as illustrations of a rapid mode of working which he describes. Primarily we may remark that these prints afford striking confirmation of our remarks in a recent article as to the possibility of rapidly drying excited carbon tissue without risk of reticulation. The tissue in this case was dried directly before the fire, and within a quarter of an hour of sensitizing was exposed under a negative, and no trace of reticulation or defect of any kind is apparent. Another important saving of time is effected which will be found valuable where dispatch is of importance. Mr. Witcomb avoids the usual operation of drying after development and before transferring, and he finds, besides practical convenience and saving of time, that the prints are in no wise injured by this treatment. He finds carbon printing on the whole so easy and so quick, and so satisfactory to the public, that he anticipates little difficulty in giving up silver printing, and adopting carbon solely for all his work. Already he says that forty-nine out of fifty of his clients prefer the carbon prints at a higher price than the silver.

This is a satisfactory statement of experience, frankly and liberally given to the community at large. Mr. Witcomb, at least, is not amenable to the charge somewhat frequently and bitterly made of late, that the Lambertype licensees were forming themselves into a separate and peculiar people amongst photographers, sworn to divulge nothing to outsiders who cannot pronounce their shibboleth. That special tuition and special privileges should be offered by the owners of the Lambertype patents to licensees who purchase these privileges is natural enough, and that it may be wise to secure the right to this tuition and other privileges, where carbon printing is adopted as a commercial enterprise, there can be little doubt. But we cannot see the wisdom or necessity of existing licensees exercising this spirit of exclusiveness. They, at least, have nothing to gain by it, neither in *kudos* nor cash. Carbon printing is a new art, and there is, and inevitably will be, for some years to come, much to learn in connection with it. The interest of all practising it must be found in the ready and full intercommunication of experiences therein. This has hitherto been the general practice of photographers, and to this rapid progress has chiefly been due. We do not for a moment suppose that this practice will cease as a general custom, even if a few persons, from some obscure motive, form a compact of secrecy. The numerous communications to our pages by Lambertype licensees show that this feeling is not by any means universal, and in our personal intercourse with M.

Lambert and his pupils we have found the most liberal and frank communicativeness at all times. Mr. Witcomb concludes his communication this week by an intimation that he hopes shortly to have further experiences to communicate, which he will impart to the little brotherhood who paid M. Lambert thirty pounds, if not to photographers generally. We have no doubt he will be better than his word, and impart to the larger brotherhood to whom he is affiliated, through the existence of which he, and every existing photographer, has acquired very much knowledge of his art without any payment at all.

PHOTOGRAPHY AND THE KORAN.

PHOTOGRAPHY has been able to solve a difficulty which has existed for many years in connection with the religious books of the Turks. The Koran, it is averred, must not be printed, but must always appear before the Faithful in written characters. Translations of the work in European languages have, as everybody knows, appeared in type, but to be holy in the eyes of the Mussulman and his brethren, the work must not be in this form. Naturally, the multiplication of copies by manuscript is a tedious and costly process, and hence the Koran is always a rare book.

But to reproduction by photography there seems to be no objection, for the copies still appear, as in the original, in written characters. Photography is so different in its nature to other modes of copying, and presents us with such a true reflex of the original, that even the most conscientious Jew could hardly find fault with a reproduction of the Koran made through the intermediary of the camera. Indeed it is a far purer mode of copying than by the quill, even in the event of the writers being men of the strictest integrity. So the art of photography—or, rather, *Lichtdruck*—has been impressed into the service, and at the present moment the firm of Frühwirth and Co. is engaged upon the reproduction of the Koran by that method. As may be expected, many strict conditions have to be fulfilled in carrying out such an affair, so that nothing may possibly desecrate the sacred writ, and the work, we believe, is supervised very carefully by those in authority.

The reproduction of the Koran in this way affords one more illustration of the characteristic value of copying by means of photography.

CARBON PRINTING.

BY GEORGE CROUGHTON.*

IN continuing the subject of carbon printing, I must apologize for the delay which has taken place between the commencement and conclusion of my remarks, which has been caused by pressure of business; but I am glad to find that others have taken up the ball and have kept it rolling.

As I presume no one would be simple enough to commence carbon printing without going to the fountain head and getting an Autotype Manual, and as Mr. W. Turner has described the various parts of the process in detail, I will confine myself to describing my failures and their remedies, and to pointing out those parts of the process which appear, in my experience, to demand especial care.

To commence with the tissue itself. To keep it in good condition it requires a deal more care than albumenized paper. I have seen it recommended to keep it in a cellar, but I have found the least damp is fatal, one of my first failures being caused by putting some pieces cut from the roll into the portfolio where the albumenized paper is always kept, and finding them stick together. A place should be found both cool and dry, and I think there are few cellars which answer to this description. I suppose it need not be added that dust and loose particles of paper, &c., should be carefully kept from the carbon surface. The bichromate solution, too, should be kept cool, and not

* Continued from page 70.

be used too often. I am using the two salts—bichromate of potash and bichromate of ammonia. I dare say adding a few drops of ammonia to the bichromate solution answers the same purpose, but I happen to have a quantity of the bichromate of ammonia, and so have not tried it yet. In taking the tissue out of the sensitizing bath in warm weather, I use the method advised by Mr. Spencer some time before he became one of the managers of the Autotype Company, viz., when the tissue has been in the bichromate solution long enough, it is drawn out face down upon a sheet of perfectly clean patent plate larger than the tissue, and the superfluous solution pressed out by a gentle use of the squeegee; it is then lifted from the glass and hung up at once, and in the hottest weather I have never found the tissue run, as it has done if lifted out of the bath and hung up without this treatment. In cold weather there is no need to take this trouble; I follow out the directions given by Mr. Sawyer, viz., after taking the tissue out of the bath it is placed face up upon blotting-paper placed over a piece of card bent into a half circle; it is allowed to partly dry, and then hung up to finish.

Want of care and cleanliness will be the cause of failure in this as in every other part of the process. The dish must be perfectly clean, the sensitizer well filtered, and no dust about; and before hanging your tissue in the sensitizing room, see that the surface is quite free from dust or loose particles of the paper, &c.

The next part of the process, the drying, is, in my opinion, the most important. I see by last week's NEWS, that Mr. Mayland can dry his tissue in thirty minutes, and yet avoid that dreadful pest, reticulation. Now most of my failures with small work developed upon collodion have been caused by quick drying, and after seeing the statement made by Mr. Sawyer during the discussion upon carbon printing, I have dried my tissue slowly, and have not been troubled with reticulate tissue. What is the cause of this discrepancy? That is a question I cannot answer. I can only state, as a fact, that when I dried quickly I was never free from reticulation; and now I dry slowly I am quite free from it. There is one thing I notice, Mr. Mayland squeezes out the superfluous bichromate before putting the tissue into the drying box; this may have something to do with it, for my quick drying has always been done in the winter, and the tissue has always been hung up direct from the bath.

But, dried slowly or quickly, it is most important that the drying should be always alike. The importance of this will be seen at once when it is remembered that the length of time the tissue taken to dry regulates the time of exposure, quick drying causing long exposure, and slow drying a quicker exposure; therefore if a quantity of pictures are to be printed from one negative, and the tissue is sensitized in two or more batches, each dried at a different temperature, it is impossible, with the best actinometer, to get the prints all alike, for the actinometer represents a certain standard of tints which is unalterable, and if the first picture printed with tissue, which has been taken, we will say, four hours to dry, takes three tints upon the actinometer; and a second is printed from a batch of tissue dried, we will say, in thirty minutes, that three tints upon the actinometer will give, with this tissue, a picture much less exposed than the first printed to the same number of tints; it will be seen, therefore, that unless some plan be adopted for drying the tissue at one uniform temperature it is impossible to work with anything like certainty.

I have adopted a very simple plan by which I dry my tissue in from four to seven hours. I have a small paraffin stove (cost nine shillings), and four boards of a certain size which stand up, the stove being in the centre; the distance these boards are away from the stove regulates the time in drying, the tissue being pinned upon the inside surface of the boards. Since using this contrivance, and resorting to slow drying, I have never been troubled by my old enemy, reticulation.

The drying being finished, see that the negative is free from dust, and the padding perfectly dry. I lost a valuable negative from neglect of this simple precaution; the damp pad caused the tissue to stick to the negative, and pulled the film up. If the tissue is too dry, you cannot get it into perfect contact with the negative.

Before going on to the next part of the process, viz., developing, it may be interesting if I describe the method I have adopted to tint the edges of the pictures without the use of cambrons and expensive printing frames.

(To be continued.)

ASCERTAINING THE TIME IN PRINTING CHROMOTYPES SIMPLIFIED.

BY J. LOEFFLER.*

When I first witnessed M. Lambert's demonstrations, the method of printing by the photometer in use appeared to me very unreliable. It also appeared very tedious, and to occasion a great loss of time, to be obliged first to print a chromotype from each negative by the number on the photometer, which, according to the printer's idea, was the right one, only to find that a mistake had been made—say, the prints were too light—and the whole operation must be gone through with again, perhaps only, on the second trial, to make a mistake in the other direction. To work a process to advantage and with pleasure, we must be certain that the result will be perfect. To make my meaning more explicit, and to show the unreliability of a meter with numbers, I give the following example:—I printed a chromotype until number 5 was well defined, and found on development that it had the proper exposure. I marked the negative "No. 5, well defined," and gave it to my printer to finish the required number of prints. He did so according to his idea of "well defined;" but every print was too dark, and, on examining the strips of paper used in the meter, I found that the printer was not to blame. No. 5 was well defined, only a little more than my No. 5; but this "little more" was probably the result of an exposure of five or eight minutes longer than mine, enough to make a great difference in the shading of a portrait. In fact, I saw that it was impossible to express in words the shade a number of the meter ought to have, so that two different persons could see it alike. Even if you do the entire printing yourself, you will find it impossible, in printing twelve pictures from one negative, to get them all alike in shade if you go by the numbers of the meter, for the reason that some of the higher numbers print very slowly, and will, during, perhaps, five minutes or more, show no perceptible difference in darkness, although those five minutes longer or shorter exposure to the light will show a great difference in the fine gradations of a face. I therefore tried to think of a surer method—one that could be understood and seen by all. During my experiments, I observed that the time required to make a print on my sensitised albumen paper, printed as dark as a silver print should be (that is, a print toned, fixed, and mounted), coincided exactly with the length of time required for a well printed chromotype from the same negative, and exposed in the same light; and this gave me the idea to use a portrait negative as a meter, which I made in the following way:—I made four exposures of a subject on a 6½ by 8½ plate, each vignette size. I gave to one four seconds, the second eight, the third twelve, the fourth sixteen seconds; developed, intensified, fixed, and varnished the negative, and backed it with mineral paper. I then numbered the four seconds' exposure No. 1, the eight seconds No. 2, the twelve seconds No. 3, the sixteen seconds No. 4. This is now my meter. As we are probably all in the habit of making proofs of our negatives, and these proofs will be made on albumen paper as heretofore, the time required for the chromotype can be ascertained while printing the proofs. Of course the negative must have the

* *Anthony's Photographic Bulletin.*

mineral paper already attached at the time of printing said proofs. I will now show how I proceed. I put the sensitized albumen paper on the negatives from which I wish to make proofs, and also on my meter negative, using very narrow strips on the meter, so as not to waste too much paper. I now turn all the frames over simultaneously, including the meter negative, and print. The negatives to be proved are examined from time to time, and the moment any of them are as dark as a finished print should be, the meter negative is examined also, and the number of the portrait in the meter which has reached the same stage of printing is marked on the back of the negative which is to be printed in chromotype, and so on, until all the exposures are found. Of course, for very intense negatives, a second intenser meter negative is required. When you come to print the chromotypes, you have only to put the chromotype tissue on your negative, and the albumen paper on your meter negative; examine the meter from time to time, and when the meter portrait whose number corresponds with the numbers of any of the chromotypes is rightly printed, turn the chromotypes over, and on development you will find that the pictures are correct in regard to depth of printing, and no loss on this account will occur. I have used this method for the last three months, and have had no failures. As I had in the beginning great trouble with this particular part of the process, I suppose that some of the other licensees have experienced the same difficulty, and may be pleased to hear of an easy way to overcome it. I must also state that on damp days in summer, when the tissue is very soft and flexible, it is more sensitive, and prints quicker; therefore some allowance in the time must be made, and the printing of the chromotype must be stopped a little before the print in the meter is dark enough. This will be only in exceptional cases, however. My method above stated will hold good for all the winter months, and most of the time in summer.

The strength of the bichromate bath and that of the silver printing bath has no doubt something to do with getting at this result; and as those using a different strength from mine ought, on that account, not to find my experience verified, I give my formulae:—

Chromotype Bath.

Bichromate of potash ... 1½ ounce
Water ... 64 ounces.

Albumen Paper Silver Bath.—Forty grains of silver to the ounce of water, with a little liq. ammonia added; the paper to be fumed fifteen minutes. I use Hovey's Rives pink paper.

It is evident that, in printing a portrait, there is only one stage when that portrait has the proper shading. Not so in printing a mere number. A number may show very plainly, and in six minutes longer exposure may not appear any darker; still the light has acted six minutes longer on the portrait which you are printing by that number, and it will have darkened, in comparison, considerably more than the number you are printing by. Therefore, that a portrait negative, as a meter, shows more minute gradations than a meter with numbers merely, is not to be disputed, and is, in consequence, a more correct criterion.

THE TRANSFER OF NEGATIVE FILMS TO PAPER.*

THE process of transferring the film from glass by means of gelatine paper, which has frequently been discussed in this journal, led me to try albumenized paper for the same purpose. The plan I found to answer excellently, whether in the case of old or new negatives.

When the negative is not varnished it only requires to have water poured over it, and then albumenized paper whose surface has been thoroughly moistened with a wet sponge is laid upon the plate, and pressed in contact with

a dry handkerchief. The albumenized paper will then bring away with it a film from the glass. Care need only be taken that when the wet albumenized sheet is placed upon the glass, no air-bubbles get underneath.

In stripping the paper subsequently from the glass, you begin at one corner of the image, where the collodion goes right up to the margin of the glass; and when necessary the border is lifted by means of a penknife or a steel pen. A preliminary dipping of the negative in a mixture of one hundred parts of water and two parts of hydrochloric acid loosens the film, but before the paper is applied the plate must be thoroughly washed, so that no trace of acid remains adherent to the film.

When the negative is varnished, the varnish is removed by placing the plate in a bath of—

Caustic potash	5 grammes
Water	60 "
Spirits of wine	250 "

The plate is permitted to remain in this bath for the space of a minute, and is then taken out, washed, and treated as above.

The stripping of the film by means of albumenized paper is a method suited for artists, amateurs, and others, and less for professional photographers, for whose work a paper basis is at times inconvenient. The former prefer to use gelatine paper, for they can then at any time re-transfer the film to glass in either sense.

The way to strip a film by the aid of gelatine transfer paper in an easy and certain manner Mr. Woodbury has already described, although that gentleman does not specify the particular kind of transfer paper he employs. But you may proceed as follows: Eighteen grammes of gelatine—Nelson's Patent Opaque Gelatine is the most suitable—are permitted to soak in cold water for some hours. The water is then poured off, and the gelatine permitted to dissolve in a water bath; gradually one hundred grammes of spirits of wine are added, the solution being stirred the while.

This solution in a warm state is applied by means of a soft brush to a piece of thin paper which is somewhat larger than the negative. The negative is well moistened with warm water, also by the aid of a soft brush, and the paper laid upon the film. Air-bubbles must be avoided.

When the paper has become perfectly dry, it is moistened with a sponge, and a corner thereof carefully lifted; then the whole is gently drawn from the glass. The paper may, when dry again, be rendered transparent, or the film may be again transferred to glass for printing purposes. Both methods are suitable for transferring films which require to be stored, and may not be wanted for printing again for a while.

Correspondence.

NOTES ON CHROMOTYPE PRINTING.

SIR,—I send you a few remarks on carbon printing, and my method of producing perfect chromotype prints in the shortest time and with absolute certainty. I do this partly as a matter of public interest, and partly in reply to numerous correspondents, whose enquiries I am not able to answer individually.

I certainly can call myself a successful carbon printer, for in my hands the process never fails, and I feel the enquiry should be, not what can be done with Autotype materials, but what cannot be done?—so sure am I that results not only far more enduring than silver, but far more beautiful and effective, can be reached, and that we are only beginning to see the great value of the new method.

My previous letters seem to have attracted a good deal of notice; and now that Sir Thos. Parkyns has, in your pages, called her attention to the speed and certainty of my

**Photographisches Archiv.*

working, and I am likely to be overwhelmed with letters, will you please let me say to correspondents that I cannot find time to give details of my methods in writing, but if any photographer is desirous of having a chromotype license, and wishes for an independent demonstration, let him come down to Salisbury, bring his own negatives, and he will find me ready and willing to show him how easy it is to produce excellent permanent prints.

And now, sir, let me repeat here what I have stated before, that nearly all the failures I see are due to using the water too hot at commencement of the development. Begin at 70°, not more, and do not soak your plates in a grooved tank, but wash up your prints in water contained in flat dishes of zinc or tin. Some will say that unless the water be tolerably hot at starting, the paper backing of the tissue will not come away. Here is the remedy. Take your prints from the frames, apply them to the collodionized glass in the usual manner, then put them under pressure for the space of two minutes only. You will find then no difficulty in stripping the paper backing, or in development; but if you keep the prints under pressure for ten or fifteen minutes, you will be simply nursing a crop of little difficulties. Try the experiment, I say, and you will soon be convinced the point is important.

As to reticulation, I very rarely see it, and cannot yet explain the reason when I do; and for want of a better reason, I am inclined to think it must be due to some fault in the material or the manufacture of the tissue. Certain I am, reticulation does not depend on quick drying of the sensitized tissue, for I have tried this repeatedly, and the causes must be sought elsewhere. As proof of this I send you herewith two cartes treated for experiment in the following manner:—

I took a piece of tissue, immersed in the chromate bath until sensitized, then removed it, face downwards, to a clean sheet of glass, drove out superfluous water with the squeegee, and then pressed under blotting-paper to absorb all moisture possible. This done, I held it, back and front, before the fire to dry, and in from twelve to fifteen minutes from starting had it into printing frame under a negative.

After exposure, soak and apply to glass, and put under the two minutes' pressure only before development. As soon as developed, fix; and, as soon as fixed, apply the transfer paper; again put under pressure for ten minutes, and you will find the image perfectly picked up—nothing lost—much better, in fact, than if the pellicle is allowed to dry before transferring. Then, if in a hurry, strip, and dry before the fire, and you can astonish a client with a perfect carbon print, mounted and complete in a very brief space of time, about two hours. This I may call the Salisbury Express C.D.V.; but, of course, I describe this experiment only to show what speed is possible, and that reticulation is not a consequence of rapid drying of sensitized tissue. I do not recommend hurry of any sort as desirable in photographic printing; but I wish your readers to note that I claim great advantages by transferring as you go along. Don't fix, dry, and transfer; but avoid the drying. You have more perfect results this way, and into the bargain it has practical convenience. You can strip all the plates of a morning, and have them all ready for the first batch of prints of that day. I find the practice so easy, and only a little more costly than silver, that I am now giving up the latter for portraits entirely, and I find the change quite easy, because my own wishes are seconded by the public taste. I have only to place before my customers specimens of chromotypes and silver prints from the same negatives, to say the former will not fade while the latter cannot be guaranteed, and forty-nine out of fifty of my clients elect to take the chromotypes at the higher price. And certainly, besides the permanency, the chromotypes are more brilliant and more uniform in colour and in tone than is possible to silver.

With regard to "full gloss," I have an idea that this would be facilitated by having a much thicker transfer

paper, say three or four times thicker than the ordinary double transfer. With summer weather coming this would quite easily dry, and if not found thick enough for use as a C.D.V., it would be easy to mount on thin card with glue or india-rubber solution, which would not penetrate the three or four thicknesses of the paper, and consequently the full gloss would be preserved to the satisfaction of the customers who desire it. I do not like it myself, but I do not ask my customers to adopt my own standard of taste. "Variety is pleasing," is an old text copy I remember; but I think the Autotype Company will do well to consider my suggestion of a thick double transfer paper for the special purpose indicated.

I have some other ideas on trial in regard to chromotype printing, which, when my experiments are completed, I will at all events give to chromotype licensees through the medium provided by the Autotype Company. Carbon printing is now a commercial question, and outsiders are not entitled to expect gratis what others obtained by purchase and experiment.—Yours truly,

C. J. WILKINS.

Salisbury April 3rd.

ARTIFICIAL LIGHT.

Sir,—The plan for an artificial light, sufficiently actinic for photographic purposes by means of a candle of phosphorus and nitrate of potash is interesting and ingenious. I regret I have not time to experiment in the direction thus indicated.

The idea, however, I may observe, seems to me very incomplete. One capital difficulty is, I fear, overlooked. When phosphorus is burnt in air or oxygen, the product of the combustion is, of course, phosphoric acid PO_4 . This new resulting substance is given off in the form of a very dense white acrid vapour, which rises round the burning phosphorus, surrounds the flame, and rapidly obscures it, and subsides but very slowly.

Before phosphorus could be utilized in the manner suggested, these objectionable fumes of PO_4 must be got rid of by drawing them off from the source of light. I fear that this would not be very easy, on account of their great density. At all events, the phosphorus candle would demand some sort of lantern and draught apparatus, and could not be used in the simple manner apparently suggested.

H. WILSON.

THE CYANIDE CURE FOR THE BATH.

Sir,—I certainly must speak out respecting the management of the silver bath, which was made the subject of a paper read at the Photographic Society last month by Mr. John Spiller, F.C.S. While not depreciating his labours to give some definite information respecting the treatment of the nitrate of silver bath, I must certainly claim to be the first person who discovered the use and addition of that chemical—cyanide of potassium—as the regenerator of a non-acting silver bath. And although at the time the then Editor of a contemporary (G. D., M.A.) protested and said it was rubbish, and was against theory. Major Russell tried it and said, "Theoretically it may be wrong, but it answers in practice." This is quite sixteen years ago—long enough to be forgotten, I admit, and of quite sufficient importance to be brought forward again. But you, yourself, published the communication in the *Photographic News*, and also referred to it in the *Year-Book*. A paper was also read by me at the Sheffield Photographic Society meeting, giving the whole of the procedure by which a truant bath could with certainty be made at once to return to its duty, and furthermore produce pure and brilliant negatives; and I shall be happy to supply in your next *Year-Book* the whole of the *modus operandi* by which any photographer can be absolute master of his bath. No pay required (you can't have anything cheaper than for nothing); no pinkies or any other annoyance after the treatment; nitrate of baryta not wanted.

I really begin to think that half the novelties are old things *hatched up again* slightly changed, not in fact, but just in a word or two, and are then claimed by some one who wishes to speak at all the meetings, be on all the committees, be on the councils, great inkling for vice-presidency, or hopes, by continual producing the output of others' brains, to be a president in time; never agree with any one, so that they can have a letter controversy in one journal or the other.

If necessary, I will try and look up the paper on the curing of the silver bath, or if you think it would be interesting to your readers, I will state the way restive baths are manipulated by yours respectfully, J. SEARS TULLY.

[We shall have pleasure in receiving our correspondent's communication. He was undoubtedly the first to propose the cyanide cure; but he overlooks the fact that we noted this in our article on the subject on March 16th, the Friday after Mr. Spiller's paper was read.—Ed.]

WASHING NEGATIVES.

MY DEAR SIR,—I send you a few lines concerning a little contrivance I use daily for washing my negatives after fixing, and as I have found it very useful in my daily work, I dare say it may be handy to your numerous readers. It is this:—A small square earthenware pot, with holes in the bottom and two on each side, for the insertion of string for the negative to rest on during the operation of washing. After the negative is fixed, I place it across the strings, put the pot in a sink, and turn on the water tap, and the negative always has a continuous stream of fresh water, as the holes in the bottom answer as a syphon. The price is, I think, ninepence for a pot which can take a five by four glass plate.—Yours very truly, C. R. P. VERNON.

LICENCE FOR CARBON PRINTING.

DEAR SIR,—Will you kindly permit us briefly to reply to the letter of Mr. Elliott, in your last issue, relative to the necessity of a licence for the practice of Autotype printing?

We beg to refer him to an advertisement from our solicitors, and to say that, sorry as we should be to disturb the good understanding that has existed for so long a time between the photographic profession and ourselves, we shall certainly take proceedings against any person or persons manufacturing tissue for photographic purposes, or offering for sale, or using such tissue (not being our manufacture), or employing the double transfer processes, without our licence or consent during the duration of our patents.—Yours most truly, THE AUTOTYPE COMPANY.

COLOUR OF CARBON PRINTS.

SIR,—I do not know what "Carbon Worker" means by saying I am a "Bogus Nemesis," nor should I have thought it necessary to explain even to him that I am not the "genuine daughter of Nox." Not content with setting himself up as an arbiter of taste in the matter of the colour of carbon prints, he now seeks to become a dictator in the matter of *noms de plume*. "Carbon Worker" says that he never set up his dictum as a standard of good taste, that he limited himself to pointing out the fact that Lambertype-purple was not a colour selected by artists for their monochromes, &c. But "Carbon Worker" did not so limit himself. He wrote, "The colour is not really good in any sense." If this is not a dictum I do not understand the meaning of the English language.

"Carbon Worker" makes a great point about some sort of secrecy which, according to him, attaches to the Lambert patents. If "Carbon Worker" knew anything about the matter, he would be well aware that in the practical working of these patents, modifications of treatment and improvements in details are suggested and incorporated from time to time. The Autotype Company have established a monthly journal which they send gratis to licensees, and in

which appears any novelty or improvement that may have been found practicable and useful. For their own interests the Autotype Company would look especially after their licensees, would endeavour to smooth their difficulties, and ensure their successful working. Surely they have just as much right to do this as to offer a commercial or any other advantage to those who are willing to become licensees under their patents.

"Carbon Worker" begins his letter by "calling names," and finishes it in a similar strain. For the future let him stick to facts, and learn some moderation in the expression of his opinion, that there may be no occasion for a request from NEMESIS.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE usual monthly meeting was held in the Water-Colour Gallery, Pall Mall, on the evening of the 3rd instant, Mr. J. GLANVILLE, F.R.S., in the chair. The minutes of a preceding meeting were read and confirmed.

CAPTAIN ABNEY, F.R.S., read a paper describing a method of intensification which was one of the best he had tried. It consisted in treating the negative first with bromide of copper, and following that with alkaline development, or with the application of nitrate of silver. The method had been brought under his attention by Mr. Warnerke, who had obtained it from the PHOTOGRAPHIC NEWS.

MR. WARNERKE, in response to an invitation from the Chairman to speak, disclaimed any credit for the process. He said: The honour Captain Abney offers me by coupling my name with the valuable investigation he made I cannot accept. I simply followed literally the formula given by the PHOTOGRAPHIC NEWS, after *Anthony's Bulletin*. However, I consider the subject of great importance, and on the invitation of Captain Abney I brought with me the result of my experiments, which illustrate well various reactions mentioned before this meeting. First is a stereoscopic negative with one of the images intensified by the described process. It will be remembered that to produce this result the photographic image is first submitted to the action of sulphate of copper and bromide of potassium, which makes it white, and blackened afterwards by the application of silver nitrate. I tried what would be the action of other metallic salts on the whitened image, and my second illustration shows that most powerful blackening action of the sepia colour is produced by nitrate of silver; chloride of gold and chloride of palladium, less intense cold black tones; still less intense—scarcely perceptible—is action of chloride of tin; while platinum chloride, lead nitrate, antimony chloride, ferricyanide of potassium, iron sulphate, iron perchloride, bichromate of potash, pyrogallol acid, permanganate of potash, uranium nitrate, have no action perceptible. Sulphantimoniate of soda renders the image red. Alkaline pyrogallol acid also blackens it. My next illustration, where the whitened image was acted on by pyrogallol acid with caustic potash, by nitrate of silver, and by ammonia hyposulphuret in three different places, demonstrates that nitrate of silver gives by far the most intense image, of very non-actinic sepia colour; alkaline pyrogallol acid, soft black grey tones, similar to the ordinary negative; hydrosulphate of ammonia, the image of light brown, tint more intense than pyrogallol acid. In every case the whites are preserved quite clear and transparent. All three methods are decidedly useful, and can be used with advantage. Having thus far found that nitrate of silver gave results better than the metallic salts, I tried chlorate of silver, sulphate, and solution of oxide in ammonia, with following results:—Nitrate the most intense, next to it chlorate, sulphate no action; ammoniacal salt a little blackening, but very unsatisfactory. My last illustration is of the action of various re-agents in the image blackened by nitrate of silver, with the following results:—Strong nitric acid destroys the blackness, but it remains still a whitish-grey image; strong sulphuric and hydrochloric acids produce no action whatever; ammonia hydrosulphuret blackens the image still more; cyanide of potassium weakens the black image, but not considerably, remaining image of still greater intensity having a purplish-black colour; iron perchloride destroys the black colour, leaving the image of a pure pink colour; ammonia has no action; hyposulphite of soda has a very feeble action. Having learned from Captain Abney's analysis that the black part forming the image is a compound of silver and bromine, I cannot omit to point out how widely different it is in appearance and

properties from the familiar white or yellow bromide of silver: (1) it is intense black; (2) it is insoluble in cyanide, ammonia, and hyposulphite of soda.

Mr. W. BEDFORD asked if the results obtained by this method were stable, as it appeared to be somewhat analogous to the mode of intensifying with mercury and sulphide of ammonia, which was not stable.

CAPTAIN ARNEY said that was a mistake; it was not analogous. In the method he had described the final result was metallic silver. In the method to which Mr. Bedford referred the final result was a salt of mercury.

Mr. WARNERKE pointed out that the black image obtained was not, as he had explained, affected either by strong acids or ammonia; and if it was unchangeable by strong re-agents, which an ordinary negative could not resist, it was clear that the treated image was more stable than an ordinary negative.

After some votes of thanks,

The CHAIRMAN said they would now proceed to the adjourned debate on the bath, and called upon Mr. Dallmeyer to open it.

Mr. DALLMEYER said he did not intend to enter into the discussion on the bath, but simply to place under the attention of readers some examples which would interest them as having some indirect bearing on the subject. Having, in common with others, heard much on the subject of the photographs of Kareline which had taken the first prize at Edinburgh, he sent to his agent at St. Petersburg, and asked him to obtain some specimens, and also any information he could. The specimens he would now place before the meeting; the process, he regretted to say, Mr. Kareline kept secret. It would be noticed that there was great depth of focus, all the figures in large groups being well defined. He came to the conclusion, from examining the pictures, that a small aperture was used: probably a lens of about twenty-four inches focus, and an aperture of about one-ninth. As all the figures seemed to have sat quite still, it would appear that he used a rapid process to secure such results with a small stop. Mr. Dallmeyer also passed round some groups taken with his D lenses, and also with the rapid rectilinear and wide-angle landscape lenses. He referred to Mr. Warren De la Rue's very rapidly taken image of the moon as having been produced by the aid of a perfectly neutral bath—a condition Mr. De la Rue laid much stress on. He noticed that present in the meeting was M. Boissonas, of Geneva, who had invented a process from four to eight times quicker than the usual method.

Mons. BOISSONAS, in response to an invitation from the Chairman, showed some albums of specimens, consisting of varied groups, and of children laughing and crying, and animals, all showing very great rapidity of exposure. He remarked that he could not of course speak of his process there, but the examples would show that it was rapid. He used for cards a Dallmeyer lens, and for the large pictures a French lens.

Mr. YONK said: Before Mr. Spiller replies, I should like to state the results of a few experiments I have made since the last meeting. I am rather sceptical about the sulphate of silver theory as to the cause of pinholes, being unable to account for the introduction of sulphuric acid into the silver bath. Dr. Vogel traces it to the supposed contamination of the sensitizing salts with sulphate of potash. I think the manufacturers of collodion would not be likely to use commercial preparations, but those specially prepared for photographic purposes. Mr. Sawyer puts it down to the sulphuric acid used in the manufacture of the pyroxyline. I think that manufacturers of collodion, knowing the destructive properties of a free acid in this preparation, would take the greatest precaution to eliminate every trace before converting it into collodion. Nitrate of baryta, when added to an exhausted bath, produces a white precipitate. It is a most reasonable conclusion to arrive at that this precipitate is caused by the presence of a sulphate. My experiments tend to show that a bath purposely saturated with sulphate of silver, which gives a marked precipitate with nitrate of baryta, does not give pinholes, but works in the most satisfactory manner. The plates produced are examples. The bath used was one which gave pinholes in abundance, until renovated by the addition of nitrate of baryta. No. 1 is the bath treated with sulphate of potash: the result is a mottled sky, similar to an over-sensitized collodion. No. 2 is another portion of the same bath treated with sulphate of soda: the result is similar, but not quite so objectionable. I then precipitated the sulphate of silver with nitrate of baryta, and No. 3 is the result, a most desirable negative with a clean sky. I then saturated the bath with pure sulphate of silver, precipitating all the nitrate of baryta; the resulting negative, No. 4, is also satisfactory, with an entire absence of pinholes. We may conclude from this that nitrate of baryta acts the part of a sanitary inspector by re-

moving the objectionable matter, and that sulphate of silver removes the excess of nitrate, thus rendering the bath comparatively pure as regards the barium salt used in correcting it. From these experiments it is important to use pure sulphate of silver, and not to generate it in the nitrate of silver-bath by the addition of sulphate of soda or potash.

Mr. W. BROOKS had obtained greater rapidity by at least four times than usual by using an alkaline bath. He took a mixture of old baths which were out of order, and added carbonate of soda until a very definite precipitate was produced. He then boiled the bath, and afterwards added a little nitric acid, still preserving it alkaline, merely adding acid until it gave a clear image, which it did long before it showed acid reactions. It was then exceedingly rapid. The alkaline bath used by Mr. Eliot practically ceased to be acid when collodion with free iodine was immersed. He used his alkaline bath with commercial collodion in usual good working condition.

Mr. SPENCER had read Mr. Spiller's paper before the last meeting with much interest. Regarding the source of the sulphate of silver, he thought it was ~~usually~~ likely to be introduced by means of imperfectly washed pyroxyline, as the presence of sulphuric acid would be shown at once in adding the iodides to the collodion. Neither did he think much would be added by impure iodides. It was most likely to be introduced in nitrate of silver. He liked the idea of using salts of barium in the collodion, and should recommend the bromide as the most easily soluble.

Mr. WARNERKE had found the bromide of barium very difficult to dissolve in alcohol. He used it in emulsions because there the same difficulties did not exist.

Mr. SEBASTIAN DAVIS referred to Mr. De la Rue's remark about neutralizing, and thought that his experiment was made when pyrogallol acid development was in vogue. [Mr. Dallmeyer: No.] Mr. Davis continued that with iron development a much larger share of acid could be used in the bath with advantage. Regarding the pinholes, he referred to a former discussion, when it was agreed that the presence of iodates in the bath was a primary cause. He then referred to the advantages of a simple volumetric method of testing the silver bath, as the method by specific gravity was not trustworthy.

Mr. BLANCHARD thought that the pinhole trouble was a growth of the last four or five years, and from some recent information he learned that during that time much of the silver used by photographers had come from a fresh source, and contained traces of other metals difficult to eliminate, such as palladium. To this cause, it seemed to him, the evil might be traced.

Mr. BROOKS thought these holes might often be traced to the use of methylated spirit in collodion and in developers.

Captain VERNY hoped the discussion would not close without a few words from Mr. Thomas, whose baths were so excellent.

The CHAIRMAN said it would be desirable to still further adjourn the discussion, and then possibly Mr. Thomas might take part in it. He now adjourned it until the next meeting, May 8.

The proceedings then terminated.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE "popular evening" of this Society was not commenced this year so early as usual in the season, on account of the many transactions connected with the late Exhibition. The first lecture was delivered by Dr. John Nicol, in Queen Street Hall, on Wednesday, 28th ult. The pictures consisted of a very fine series of transparencies by Messrs. G. W. Wilson and Co., of Aberdeen; and, in spite of a very rainy night, there was a large audience.

Dr. NICOL stated that the subject of exhibition was suggested during a pleasant trip made by the Treasurer and himself to the "Granite city." He spoke in the highest terms of the city and its inhabitants. Among the chief objects of interest were views of Dunottar Castle, and two views of the city from the chain bridge. These were followed by a large series of pictures of the principal streets and buildings, the famed "Brig o' Balgonie," Inverogy, and Ravenscraig castles. Then, returning by the Bridge of Dee, a series of fine pictures of the district known as "Deeside," extending from Aberdeen to above Ballater, was exhibited—when Dr. Nicol's remarks were suddenly brought to a close in consequence of the gas refusing to do further duty. A small leak had taken place in the gas bag, which had not been in use for a considerable time. Such accidents will occur, even amongst the best regulated.

If late in beginning, the "popular committee" seem to have lost nothing of their old zeal, as they have issued tickets for the 11th inst., when an exhibition of "The Arctic Expedition under Captain Nares" will take place.

Talk in the Studio

PHOTOGRAPHS OF "CELEBRITIES."—It is said that among the number present at the execution of the Mormon Lee was a photographer, on observing whom, preparing to take a photograph of him, the prisoner observed: "I want to speak to that man. I want to ask a favour, sir. I want you to furnish each of my three wives with a copy of the photograph." As a further specimen of photographic enterprise in the portraiture of "celebrities" may be recorded the case of William Stevens, known as the Buckinghamshire giant, for whose photograph, taken two days before his death, a large sale is anticipated among those whose extraordinary taste led them to supply him freely with the food and drink which, no doubt, caused his comparatively early death at the age of 49. He was, it seems, about 5 feet 10 inches high, and weighed 35 stone.

A PHOTOGRAPHIC KORAN.—At a time when preparations are being made for a Caxton celebration, and for commemorating the four hundredth anniversary of the introduction of printing into this country, an instance arises, strangely enough, which shows us that there are still branches of literature that the art has failed to assist in spreading. The Koran, according to the Mohammedans, must never be printed, but always appear before the Faithful in written characters, a circumstance which has stood in the way of its very general dissemination. Every copy of the sacred book is produced in the same way as copies of other writings before Caxton set up his press in this country. From Germany, however, the news comes to us that the time-taking and laborious work of making copies of the Koran in manuscript has at last come to an end. Although type and the compositor's frame are forbidden, there is no such prohibition against the employment of photography for the purpose, and it is to this art, in preference to that of Caxton, that high Mohammedan functionaries have turned to solve a difficulty under which they have laboured for some time past. Here there is no transposing of the writings into modern characters, or setting them by having recourse to type and letters which were unknown at the time of the great prophet. As in the copying of the Domesday Book, the Utrecht Psalter, and other rare works, the original need merely be set up against the light, in order to be copied trustworthily and truthfully with the camera, the photograph obtained being subsequently transferred to stone or zinc by any of the well-known processes at present in existence. Once properly transferred in this way, the image may be multiplied and copies struck off as rapidly and as plentifully as in the case of ordinary lithographs or zincographs. As regards the special reproduction of the Koran in this manner, the most stringent measures have been taken by those under whose direction the work is proceeding to prevent anything that might be considered as a desilement of the ancient document. The art of photography applied in this manner is of such a nature that the chances of introducing extraneous matter are in the highest degree improbable.—*Daily News.*

LETTS, SON, AND CO., Limited, whose name as publishers of diaries has for so long been associated with the Royal Exchange, have removed to No. 33, King William Street, London Bridge.

To Correspondents

IGNORAMUS.—You are entirely under a mistake as to the origin of carbon printing. Mr. Fox Talbot never made any attempt in that direction. The discovery of the principle upon which carbon printing depends was made by Mr. Mungo Ponton, in 1839. He discovered the sensitiveness of paper treated with bichromate of potash. Fox Talbot applied this principle to the invention of an engraving process. M. Poitevin applied it to carbon printing, and patented his process in this country in 1856. Many others worked in the same direction, but they failed to secure half-tone in the prints. It was reserved to Mr. Swan to discover a practicable method of producing carbon prints with half tone, in 1864. A patent once secured is at first granted for three years; at the end of that time, on payment of certain stamp duties, it is extended for four years more; and at the end of this time, on further payment, for seven years more, making fourteen years. It then expires, unless the patentee petitions Her Majesty for a further extension, which, under some conditions, is granted for seven years more. Your print produced on tissue, made ready sensitized, and kept for three months, is very excellent. Without the publication of Mr. Swan's invention the production of such a print would have been impossible.

J. H.—The best glass for studios is the whitest. The Belgian sheet, which is the cheapest, is also very colourless, and is the glass we should use.

STEREO.—The coating of paraffine inside your tub will not be injurious to the prints. 2 You may produce stereoscopic pictures by means of one camera. To do this efficiently and satisfactorily use Latimer Clark's parallel bars, which permit the camera to be moved without disturbing the focus or altering the position of the image on the ground glass. The arrangement you propose, of moving the lens through a slit in the front of the camera, would not answer well, and would give too little variety in the angles for stereoscopic effect. 3. We cannot tell you where you can purchase lenses for a stereoscope. Try any optician.

C. WILSON.—We have no means of forming an opinion of the state of trade amongst portraitists in Australia, or of the openings for a portraitist. We have no doubt that openings exist for good men.

J. P.—In proceeding against a person for piracy of your works, your best plan is to place the matter in the hands of a respectable attorney, who will take the necessary steps. A summons must be issued against the infringer by a magistrate, who will grant it on sworn information. The complaint must be brought under 25 and 26 Victoria, cap. 68. Your attorney, or his agent, can obtain a certified copy of the registration by application at Stationers' Hall, stating date and details.

FLORENCE.—There is no reason why your silver bath, made twelve months ago, should not work perfectly. 2. One of the simplest and most efficient dry processes you can try is the coffee process, described in several articles in our last volume by a correspondent at Ouchy. You will find the process in a complete form in our last YEAR-BOOK. It is simple, and the results excellent. 3. The liquid glue in question is said to be made by boiling a good sample of ordinary glue for some time, and adding a few drops of nitric acid. Then cork up in bottles.

F. RICHARDSON.—We have often recommended operators not to send their specimens to unknown persons. As a rule, we know nothing of advertisers to whom communications are to be addressed at our office. They send their announcements, and call and receive replies. The most common reason why specimens are not returned is the absence of a stamped and addressed envelope in which they may be returned.

AMATEUR.—We have published many articles on the production of collodion transfers, both in the NEWS and in our YEAR-BOOKS. You will find some details in our YEAR-BOOK for 1872, page 97, and in various other of our YEAR-BOOKS.

A. P.—The statement that no licence is required is untrue and misleading. The processes, being protected by patent, cannot be practised without the licence of the patentee. If the statement be meant to imply that the patent is not valid it is of no value, but merely an *ex parte* expression of opinion. Possibly it is meant to imply that no licence is required for taking lessons; but in that case, since a licence would be required for practising the processes, the statement is misleading. Possibly it is meant to imply that no licence is required for teaching; in which case the statement is practically without meaning. See announcement by Autotype Company in our advertising pages.

J. W.—Allow the paper to float on the silver bath about three minutes. This is a matter which varies with circumstances, which you will understand better as you gain experience. A saturated solution of anything is as much added as the liquid will dissolve. For instance, one drachm of ordinary carbonate of soda will make a saturated solution if added to a drachm and a-half of water; or if bicarbonate of soda be used, one and a-half ounces will make a saturated solution of 12 ounces of water. A 20-grain solution of the common carbonate will serve for treating the blotting-paper.

ARAX.—The cause of your failure is in the quality of the pyroxyline. Neither sample has been suited for making collodion. If your solvents were insufficiently rectified, the presence of water would increase both the defects you name. But the opalescence and the glutinous quality are common faults of a bad sample of pyroxyline, generally of a sample made at a low temperature. It is difficult to advise a remedy, inasmuch as in our experience it is difficult to purchase good samples of pyroxyline. We have generally found it desirable to prepare our own. We have repeatedly given formulae for its preparation, especially in back YEAR-BOOKS.

W. SPILSBURY.—Notification of the receipt of P.O.O. was duly forwarded.

W. R.—No credit was given at the time. Of course we shall not notice such a person.

THOMAS GAFFIELD.—Many thanks for papers duly received. We have already made some extracts on the subject, and shall probably make more.

P. G. A. (Kewick).—We have examined the mounting board, and see no reason to doubt its fitness for photographic mounts. The spots on the prints are very perplexing, and very difficult to trace to a certain cause, as similar spots arise from various causes. Particles of the bronze powder used in "gold" printing names and addresses produce very similar spots: impurities in the washing water yield similar results; sometimes the burning of a coke fire in the printing room, giving out sulphurous particles, will produce a similar crop of spots; sometimes a defective sample of albumenized paper, especially if it have been kept for a few months in a damp place.

Several Correspondents in our next.

The Photographic News, April 13, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHY AND THE HEALING ART.—WHAT TO DO WITH HARD LANDSCAPE NEGATIVES.—THE PLANET VULCAN.

Photography and the Healing Art.—Medicine and photography have much in common in respect to the materials employed in their pursuits. Collodion is eminently useful both to the medical man and the photographer, and is at the same time rarely employed by anyone else. If statistics in the collodion manufacture were collected, we doubt not that these would show that the material was almost exclusively used in surgery or photography. Although a product but recently discovered, it is one now of the most important materials employed by the photographer and the surgeon. Another case may be cited almost parallel. Bromide of potassium, which was so little known and used fifteen years ago that the imports into this country amounted to but sixteen pounds' weight in the year, has steadily increased in favour—both as a medicament and as a photographic chemical—that, at the present moment, no less than one thousand six hundred pounds of the salt are annually introduced into Great Britain, while other large quantities are manufactured in England itself. We need not point out to our readers the value of bromide of potassium in photography, for the salt is too well known to need any explanation on our part. Neither need we allude to the increased use that has been made of the compound during the past two or three years, since the introduction of alkaline development and the preparation on every hand of bromide emulsions. In medicine the salt has been received with the same favour. In cases of epilepsy it works wonders, and is administered by all medical men now-a-days with considerable confidence. In the same way as iodide of potassium has proved beneficial to eradicate stubborn influenza, and to promote secretion in the tissues, to benefit our seeing and hearing faculties so the administration of bromide proves efficacious in epileptic disorders. Following in the wake of the photographer, who did not hesitate to essay the effects of a bromo-iodide in his work, and thereby combine the good qualities of both salts, medical men have now had recourse also to bromo-iodide of potassium, employing the double salt for cases of goitre and other similar diseases. Balard, the late president of the French Photographic Society, and discoverer of bromine, who died during the past twelvemonth, lived long enough, fortunately, to see the benefit his discovery had conferred upon his fellow men. When he first made known to the world fifty years ago that he had found out another chemical element, it seemed as if, but from a scientific point of view, the discovery was all but useless. When a young man at Toulouse, he noticed the formation in some disused salt pans of a salt which turned out to contain a new element, and it was in investigating this new element bromine and its compounds that the great French chemist spent most of his life. Had he paused, like some might have done, to ask of what good the whole discovery and investigation might be, photographers and medical men would not at this moment be in possession of a most valuable compound; for it is but recently, as we have seen, that any extensive use of the salt has been made. It is gratifying to think that M. Balard lived to see the fruits of his labours fully appreciated.

What to do with Hard Landscape Negatives.—One of the late M. Constant Delessert's hints in regard to landscape photography may well be revived for carbon work. That clever experimenter exhibited at Paris, some eight or ten years ago, a series of landscape pictures rather larger than cabinet, and printed upon salted drawing paper. Not only was the surface rough, as in the case of Whatman and similar sketching papers, but it was, moreover, tinted from cold grey and green, in some instances, to a warm rose in others. The effect of lake and mountain pictures printed upon a

rugged tinted surface was, in many instances, very agreeable, and some of M. Constant's photographs had all the effect of little sepia or water-colour sketches. The rough texture of the paper broke up any monotony where this might exist, and, especially in the skies, had a most pleasing effect. M. Constant employed both plain salted paper and also paper prepared by the shellac process, in producing these little pictures, and selected his tints according to the nature of his negatives. To amateurs more especially is the use of tinted paper to be recommended where the negatives happen to be somewhat hard and the high lights otherwise too glaring and chalky. In employing the carbon process it must be the transfer paper that is tinted. But, in any case, the tint employed must never be deep, and care in mounting and framing must be exercised, so as to heighten, and not degrade, the result. In the case of indifferent negatives, much more pleasing pictures may be secured by such a method of printing than by having recourse to perfectly white paper in making the prints.

The Planet Vulcan.—Photo-astronomers, having been called upon throughout the length and breadth of the globe to adduce testimony for or against the presence of a new planet, which has already received the name of Vulcan, seem to have afforded negative evidence. For some time past the existence of Vulcan, a planet supposed to revolve around the sun, inside Mercury, has been discussed, and in France a good deal of credence has been felt on the subject. The eminent French astronomer, M. Janssen, has for months past been watching for the expected planet, and arranged his automaton *revolver photographique* with a view to securing proofs of its existence. Marks of one kind and another have been found to appear upon the sun's disc, which French astronomers avowed were not spots, but a recurrence of this planet, and as it was asserted that on the 22nd of March the planet would again make its appearance between the earth and the sun, photo-astronomers of all nations were asked by the Academy of Sciences to take as many photographs of the solar orb on that day as possible. Sir George Airey, the Astronomer-Royal, as the British representative of men of science in this country, particularly urged that the request of our French brethren should be complied with; but the 22nd has come and gone without anyone having observed the long-looked-for planet. We fear, therefore, that its existence is only to be found in the sanguine imagination of our French confrères, and that we must still be content to number Vulcan among other well-known myths. Whether the phenomenon that has been taken for it is an ordinary spot on the solar disc is, however, another matter; but it is one which will doubtless very speedily be solved by the aid of photo-astronomy. In fact, in the branch of science appertaining to the study of our heavens, the help of the camera is now almost indispensable. Optical observations may do much in confirming or reconnoitring; but for adverting absolute proofs of this or that phenomenon there is nothing like the sensitive plate. All recent study of the sun, of its photosphere, its corona, and protuberances, has been rendered more accurate and trustworthy by the aid of the camera, which has permitted researches such as could not have been conducted without its aid. The establishment by the French Government of a photo-astronomical observatory at Meudon, to which we recently referred, in an additional proof, if any were wanted, of the great value of photo-astronomy.

FRENCH CORRESPONDENCE.

THE DRY-PLATE COMPETITION IN PARIS.—AWARD TO M. CHARDON FOR AN EMULSION PROCESS.—THE SILVER BATH CONSIDERED THE SOURCE OF FAILURES IN PRACTICE: ITS SUPPRESSION.—M. BOIVIN'S FORMULE AND PROCESS.—BLETTES OF ALBUMENIZED PAPER.—ADDITION OF AMMONIA TO THE FIXING BATH.

IN the course of the year 1876 the French Photographic Society instituted a competition among photographers

for the best dry collodion process uniting rapidity with all the other qualities which go to make a good cliché. The author who obtained the prize was to give the description of it in every particular, so that the method might subsequently be given to the public. The competition closed in December last, and the result of the jury was made known in Paris last Friday evening. Only three competitors presented themselves. Their processes were put to a practical test, at the end of which only one was found to fulfil the conditions of the programme. The method was one proposed by M. Alfred Chardon. On the same evening, after the report of the jury had been read, the successful competitor gave an account of the process, and demonstrated the working of it before the members of the Society. As M. Chardon himself admits, the process has nothing new in it actually. The improvements he has effected consist in defining the proper proportions of ingredients to be employed, in the happy application of the reactions produced, and in the singular care that has been taken in the preparation of the various compounds. Without entering into details, which will be found in *extenso* in the report that is to be published shortly, I may say that the method in question is based upon the employment of an emulsion which is dried after it has been prepared, being re-dissolved at any time when it is necessary to undertake the preparation of plates. This emulsion contains bromide of ammonium, bromide of cadmium, a bromide of zinc, and, after having been sensitized, it is freed from all excess of silver. The different manipulations necessary in the preparation of the two collodions that are mixed at a certain moment, the dissolution of the nitrate of silver and its addition to the collodion, the process of drying, and the second solving of the emulsion—all these are a little complicated; but it must be admitted that, on the other hand, there is no preparing of a preservative of any sort, this being altogether suppressed in M. Boivin's method. The exposure necessary is but twice that necessary in the case of wet plates. The development is alkaline (carbonate of soda and bromide), with pyrogallie acid to finish with. In a little while I hope to send your readers full details.

The success of M. Chardon will, necessarily, produce in this country a disposition in favour of emulsions, which till now, has had but few disciples here. M. Boivin, whose name, I am sure, is familiar with the readers of the PHOTOGRAPHIC NEWS, and who is one of my own collaborateurs, has been for some time past one of the most earnest advocates for the suppression of the nitrate of silver bath. He attributes to the latter (not without reason) the greater part of the accidents and failures which happen in everyday practice. He has recently sent me a description of the emulsion process which he now employs both for wet and dry work with equal success. The collodion is compounded in the following manner:—

Water*	60 cub. cents.
Alcohol	40 to 50 "
Pyroxyline, prepared at a high temperature	1.50 grammes
Bromide of zinc or ammonium	1.50 "
Bromide of uranium...	1.50 "
Chloride of barium...	0.10 "

The collodion, after standing for some time, is filtered and poured into a bottle containing four grammes of white fused nitrate of silver dissolved in a little water and alcohol. The bromide of silver formed thus, in the presence of an excess of silver, is much more sensitive than when it is formed in the presence of an excess of bromide. The mixture is allowed to stand for some days, taking care to shake it up from time to time, and it is filtered through cotton wool. The bottle containing the emulsion must be preserved in the dark. Before using it should be shaken up, and then permitted to stand for ten minutes.

* No ether is mentioned.—Ed. P.N.

The emulsion collodion must be poured upon the plate in a rather more liberal manner than is the case with ordinary collodion, and the glass should be kept a little longer in its horizontal position. When the film has well set, the plate is plunged into a bath of rain-water, and when taken out, it is rinsed by the aid of a wash-bottle. If you are not going to use the plate at once, it is treated with an organic preservative, and allowed to dry.

In order to develop, M. Boivin pours into a quarter-plate bath sufficient water to cover the plate, and adds to it three drops of ammonia, and five drops of a ten per cent. solution of bromide of ammonium. The plate is plunged into this bath for the space of a minute, and then five drops of pyrogallie acid are added (10 parts of acid dissolved in 100 parts of alcohol), the liquid agitated, and the plate again treated. The image appears after the plate has remained immersed for a little while; first of all the pictures appears by reflection, then disappears, and afterwards is seen as a transparency.

In warm weather, and when the exposure is long, it is necessary to augment the amount of bromide added; it is diminished, on the other hand, in winter, and when the exposure is short. According to M. Boivin, the bromide plays here the same rôle as acetic acid in the ordinary developer. The ammonia is the active agent, while the pyrogallie acid is simply the reducer.

If the image has a tendency to become fogged, it is necessary to add a few drops of the bromide solution; if details are wanting, then some more pyrogallie acid is added. When the image is perfect seen as a transparency, but a little weak, it is well washed first of all in pure water acidulated with a little acetic acid to remove all trace of alkalinity, and finally it is intensified with pyrogallie and silver. Finally the image is fixed with hyposulphite of soda.

In general, the formulæ given are only employed by M. Boivin when working with wet plates, the silver bath and its attendant inconveniences being in this way obviated. But in the case of dry plates, the first part of the preparations being capable of being made in the studio, he prefers to employ the same collodion as above, sensitized in a silver bath of fifteen per cent. strength, with 0.50 per cent. of nitrate of uranium. He proceeds then as in the case of an emulsion, except that after washing the plate he passes over the film a solution of chloride of barium, made by dissolving one part of the latter in 1,000 parts of water. Another rinsing with water succeeds, and then the preservative is applied. The rapidity in this case is greater than with the emulsion, and the clichés are finer.

Apropos of the means indicated by M. Andrés to prevent the formation of blisters in albumenized paper during the last washings (a method of which I made mention in my last letter), I may refer to another, which is more simple still, and which is made use of by some of the best known of our portraitists—MM. Walery, Nadar, Disderé, Lumière, of Lyons, &c. It is as follows:—The fixing bath is reduced to eight or ten per cent. of hyposulphite of soda, and there are added five grammes of liquid ammonia per litre. The manipulations are precisely the same as usual, and the results are excellent. Nevertheless it seems to me as if the final tint of the prints must be changed by the action of ammonia, a matter that renders some modification of the toning bath necessary.

ERNEST LACAN.

PORTRAITS IN WATCH GLASSES.

A PORTRAIT which is acquiring considerable vogue in the United States at present is described in *Anthony's Photographic Bulletin* as follows:—

"Take an unmounted rather strong print, and trim the same somewhat smaller than the convex glass to be used; wet it thoroughly in clean water, and then lay it face up on

a sheet of glass, blotting off the water; then brush over it a stiff paste, made out of gum tragacanth, and apply the same also on the inside of the convex glass, which ought to be carefully cleaned with ammonia; then lay the print on the glass, and on the top of the print a piece of smooth, tough paper, and rub out all the paste and air-bubbles with an ivory or bone paper-folder, the upper edge of which must be curved corresponding with the shape of the convex glass; the edge must also be sharp and smooth. Always work from the centre, using slight pressure, and frequently change the smooth paper on the back, which serves to protect the print from getting scratched and torn. After the print is perfectly mounted without showing either wrinkles or blisters, let it dry thoroughly, but spontaneously. Then grind the paper a little with fine sand paper, and immerse it in a small tin pan containing molten spermaceti (a good plan is to have the pan fitted into another pan holding a water bath, in order to just keep the spermaceti in a molten condition without heating it too much, in which case it would affect the albumen of the print, turning it into a nasty yellow that will spoil it entirely). It will only take from ten to twenty minutes to make the print perfectly transparent; then take it out of the spermaceti and let it cool off, and with a coarse rag rub off all the surplus spermaceti, laying the glass on a small cushion to avoid breaking. Now the picture is ready for painting. All white drapery, such as collars, facos, shirts, &c., also the corners of the eyes, are painted on the back of the photograph with flake white; jewellery, lips, eyes, flowers, and similar things are also coloured on the picture itself, only care has to be taken to keep exactly to the outline. When this part of the colouring is done, take a second convex glass, put it over the photograph on the back and fasten the edges with adhesive paper; then mix the flesh colour, and on the back of the second glass paint all over the face; then paint over the hair, to make it the tint and shade desired; the same is to be done with the drapery and all other parts of the picture. It is more convenient to do this work on a negative retouching-frame, in order to preserve the outlines better. When painted, back with cardboard.

"Mr. Kraus, the introducer of these pictures, contends that the formula already published, based on his original invention, are defective, for the reason that castor oil causes the pictures to become more or less opaque, especially after a few months' keeping. Spermaceti, on the other hand, will make them endure indefinitely."

ON A NEGLECTED METHOD OF INTENSIFICATION.

BY CAPTAIN ARNEY, R.E., F.R.S.*

SOME three or four months ago I had the pleasure of a visit at Chatham from Mr. Warnerke, and in the course of some experiments with his tissue, he introduced to my notice a method of giving intensity to a negative which, as far as I know, has not been practised to any great extent in this country, but which to my mind is superior to any that I have as yet tried, including the ferro-cyanide of lead intensifier. The method of procedure is as follows:—To a saturated solution of copper sulphate is added a sufficiency of potassium bromide; and when I say sufficiency, I mean a quantity which is capable of converting nearly all the copper sulphate into potassium bromide. At ordinary temperatures an ounce of water will dissolve one hundred and twenty grains of copper sulphate.† It, will, therefore, be necessary to add about one hundred and twenty-five grains of potassium bromide (dissolved in a small quantity of water) to effect total decomposition. The exact quantity is immaterial, but the dose of bromide should not be spared. Personally I prefer to use at once a solution of copper bro-

mide, by decomposing barium bromide with copper sulphate, or by acting on copper oxide with hydro-bromic acid. In this case a solution of one hundred grains of the salt to each ounce is of sufficient strength. Having secured a solution of copper bromide in one of these ways, the developed and fixed plate is flooded with it, and allowed to act till the grey metallic silver becomes of a white appearance. When this is obtained, the plate is washed under the tap till the green colour of the solution no longer tinges the water, and until the addition of ammonia causes no distinct blue colour in the wash water. After arriving at this point, two methods of proceeding are open. The plate may be treated with alkaline pyro-gallate, when there will be an evident gain in intensity. So far as this the method of intensification is similar to that described in the *British Journal*, in which copper chloride is employed instead of the bromide. Instead of giving intensity by the alkaline pyro-gallate, another method is open. This consists in flooding the bleached plate with a strong solution (say of one hundred grains to the ounce) of silver nitrate. An intense black results; so deep is it, that in general it is more suitable for the intensification of line engraving negatives, than for half-tone negatives. With an emulsion giving a thin negative, however, it is invaluable.

When I saw the action of this intensifier, I was puzzled as to the reaction that took place; and finding it absolutely impossible to get a satisfactory analysis from the deposit on a plate, I precipitated silver, and treated it in the same manner, and analysed the compound at each stage of the proceeding. The results obtained are remarkable, and well worthy of attention. On addition of the copper bromide the following reaction was observed:—

1 equivalent of silver + 1 equivalent of copper bromide gives 1 equivalent of silver bromide + 1 equivalent of sub-bromide of copper.

Or—

On exposure to the light, the compound darkened readily, giving secondary evidence the silver was in this state. In one or two analyses I thought I had found that the one equivalent of bromine from the copper bromide had combined with two equivalents of metallic silver; but eventually I found that invariably when the reaction was complete, the whole of metallic silver was converted into bromide. When the above compound was treated with silver nitrate, we have a remarkable reaction. The sub-bromide of copper combines with the silver nitrate and forms silver sub-bromide, thus:—

The question as to whether sub-bromide of silver was really formed, or whether it was not merely bromide with 1 atom of deposited silver, was at first difficult to answer; but I think I have satisfactorily proved the presence of the sub-bromide. Had there been metallic silver present, it would have been possible to pass a spark from a Ruhmkorff coil through the compound, the small atoms of silver would have acted as steps by which it could pass. This was proved to be impossible, and, moreover, the current from a strong battery would not pass through the compound even when heavily compressed. I may state that in a mere mixture of bromide and metallic silver the spark passed.

When treated with ammonia, the compound split up into AgBr and metallic Ag. Nitric acid was also able to decompose the Ag₂Br, as was potassium cyanide. It need scarcely be said that no mixture of silver bromide and metallic silver would give the jet black appearance I have indicated, though a mixture of blue colour of the sub-bromide and the yellow of the bromide would do so. It was also noticeable that after treating the supposed Ag₂Br with ammonia, the metallic silver separated out in spangles much larger than the original particles of metallic silver. In the case of a simple mixture of the bromide and metallic silver, I do not think this phenomenon would be observed.

* Read before the Photographic Society of Great Britain.
† It must be remembered that copper sulphate is combined with five equivalents of water.

When the intensity is caused by the application of alkaline pyro-gallate we must look for a different reaction. Though you have the sub-bromide of copper present, it is soluble in ammonia, and can all be washed away, and probably is, if the washing be effectively done. In this case the intensity is gained by a re-arrangement of the atoms of silver, for there is only the same amount of silver present to be reduced as there was originally on the negative. In this case, then, we have a gain in intensity caused by a physical process more than by a chemical. Where long washing of the white compound is resorted to, I am not prepared to deny that part of the image may be formed of metallic copper. For another point to which I wish to call your attention is this:— CuBr is said to be insoluble in water, yet you may go on washing the bleached precipitate for days, and still you will find traces of copper bromide in the wash water. After some trouble I have found that the sub-bromide is rather unstable, tending to pass into the bromide and metallic copper, thus:—

Eventually, of course, the metallic copper is converted into oxide.

In preparing plates on which to secure photographs in the same method has been adopted, substituting the chloride for the bromide, and the following are the phenomena observed; the copper chloride bleaches the metallic silver on the plate, and gradually the bleaching gives place to a rusty tint, and this probably is due to the reaction indicated above. As this is part of the same method, already indicated, of obtaining intensity, it would follow that the image may be partly metallic copper, even before treatment with alkaline pyro-gallate.

To Mr. Warnerke belongs all credit for bringing this method of intensification to a knowledge of the society, for had he kept his treasure to himself, as is too often the case with some who get hold of "a good thing," I should not have had the satisfaction of referring to it to-night. Mr. Warnerke informs me that he found the treasure in the *Photographic News* amongst some American correspondence. I advise every one to give it a fair trial. At Chatham we infinitely prefer any process of intensification which gives the desired opacity without the necessity of converting the silver and other metal into sulphides. My experience has shown that all such are unstable to a greater or less degree.

DRAWBACKS.

BY E. DUNMORE.*

FINDING this evening we have no paper—in hunting phraseology we have drawn blank—I will try to supply the hiatus by a few memoranda that may, perhaps, give rise to some discussion. Of course, this paper is prepared under considerable drawbacks—the drawback of short time for consideration, the drawback of not having any books of reference, the drawback of having nobody else's writings to con over and appropriate under a new title; and, also, the drawback of serving it printed with all errors that may creep into such a rapidly-prepared paper. With all these drawbacks, I think I cannot do better than entitle this paper "Drawbacks." If I make any very glaring errors, I must ask you to look over them.

The first little matter that occurs to my mind is that of a plan for curing the reticulation of the collodion film when it is produced by solvents containing too much water, and which has gone the rounds of the photographic literature of the day. It is as follows:—"Place in the collodion to be cured a few strips of dry gelatine; this will absorb the water and the collodion will be rendered serviceable." Now, if this would absorb the water, no doubt the plan

would answer; but, as it will do no such thing, there is a considerable drawback to its general adoption. It was a simple matter, so I tried it. Several months passed by—no difference. At the end of twelve months, save and except the gelatine appeared rather more opalescent than before, no alteration had taken place. I added a fourth part of water to this collodion and gelatine, and let it stand some months longer, and the result was that the gelatine had not absorbed any—or, at least, sufficient—water to make any appreciable difference to the bulk; but it had become a pasty mass at the bottom of the bottle. What changes had taken place I am unable to say, and merely record the fact.

The permanency of silver prints has always been a matter of serious consideration with photographers, and any plan that would tend to give increased permanency was, and is, hailed with delight. Some nine or sixteen years ago Mr. Spiller recommended the addition of ammonia carbonate to the hypo. fixing bath. I felt very chary at expressing my opinion on the matter, having had comparatively small experience, although I had made a practice of adding it previous to Mr. Spiller's recommendation, but with a different intention. The idea was that hypo. in solution was apt to be acid and detrimental to the prints; so I used carbonate of soda, or ammonia, as the case might be, for the purpose of correcting this acidity. After hearing Mr. Spiller's paper, I invariably used the ammonia, and with great advantage as regards permanency. Some proofs then prepared have remained as bright and good as on the day they were prepared. During the past eighteen months I have used as much as two hundredweight of ammonia carbonate, and, as far as the matter of permanency, with, I have no doubt, good effects. But here comes the drawback: it was found that when the proofs so fixed were washed and dried, on careful examination (I say "careful examination," as the fault was very difficult to detect), a peculiar bloom was found to cover the whole face of the negative with marks and smears of a dull appearance here and there. Till these proofs were mounted the fault was not noticeable, but when they had been mounted these dull marks were very great eyesores, and necessitated each proof being rubbed over, the deposit, whatever it was, being removable by this means. Perhaps some gentleman present has had similar experience, and can suggest a remedy; for the present I am quite unable to suggest a cure, and this drawback is such that will prevent an otherwise useful modification of the fixing bath to be used where a large quantity of work has to be got through.

I have seen cyanide of potassium recommended in dilute solution for cleaning negatives that have got soiled with silver stains from hard work—small particles of the silvered albumen adhering to the cliché, and making white specks. There is no doubt whatever that the remedy will be, and is, efficacious; but here is a drawback, unless the varnish of the negative be very hard: the cyanide is apt to dissolve it sufficiently to attack the negative beneath, and utterly destroy it. Great care is, therefore, necessary to be taken in ascertaining the protective power of the varnish. Several applications of a rather strong solution are frequently sufficient to injure most negatives. This plan, however, used with extreme caution, is undoubtedly serviceable.

Of course there are many other drawbacks to processes that have been recommended for the benefit of photographers, but time is too short to permit allusion to them; therefore I will, with these few remarks, conclude, and leave them for discussion.

One little matter that scarcely comes under the head of "drawbacks" is the possibility of developing an ordinary wet plate by the alkaline method. In making a few experiments with the intention of causing a wet plate to keep moist and sensitive, I gave an ordinary sensitised film a coating of albumen and glycerine in the proportion of one

* Read before the South London Photographic Society.

ounce each to half-a-pint of water. Mr. William Bedford suggested development with the alkaline method, which I carried out, and found, although the negative seemed rather poorer than I should have liked, it came out very fairly satisfactory.

LANDSCAPE PHOTOGRAPHY.

BY JOHN PARKER.*

My earliest attempts at landscape photography (and it is only to that I have given any attention) were with a Newton's camera, eight by ten, and a long focus Ross' lens of three inches diameter. The sensitizing, developing, and clearing baths were all, as in Newton's, suspended below the camera, the whole thing being an immensely unwieldy affair, to carry which I had to utilise the tripod legs, on which it was suspended by straps, and carried by the aid of a friend, exactly in the fashion of a mason's hand-barrow, or a miniature sedan chair of bygone days. The method of working such a camera—apart from its cumbersome—proved unsatisfactory in the extreme. I next got a folding camera—portable by contrast with its predecessor, but still a bulky and troublesome affair, and, together with a tent, chemicals, &c., making such an amount of impedimenta as to rob an excursion of all its pleasure.

Several varieties of tent and sizes of camera were contrived, each improving some defect in its predecessor, and I succeeded in getting some fair work; but the cost and labour far exceeded the results, and were it not for an ardent love for the work, and an insatiable craving after the beauties of nature, I would have given it up in despair.

Dr. Taupenot's collodio-albumen formula for dry plates gave me the first relief. I tried it, succeeded—to my own satisfaction, at any rate—and discarded my tent and wet plates for years. Taupenot's process had one fault, however, in its great liability to blisters; and these sometimes sadly annoyed me, though I took every precaution, gave a preliminary coating of dilute albumen to the plate, and adopted every likely suggestion as a remedy for the evil. Fortunately, however, the blisters generally dried flat, so as not materially, if at all, to affect the printing qualities of the negative. But it was sometimes otherwise, and a negative which at first promised to be perfect would, when finished, prove useless.

Two or three years ago I was induced to try a modified collodio-albumen process, known as "Dr. Hyley's Hot-water Process," and on plates so prepared I have not known the annoyance of a single blister, though since I first tried it I have prepared many plates. Indeed, except a few experimental beer-and-albumen plates, I have confined myself entirely, for dry plates, to the "Hot-water Process" ever since; for my opportunities for photographic work are too rare to permit of wasting them in experiments in untried processes, however much recommended, and I attribute any success I have had to this sticking to one process. Where the object is to take good negatives, I would strongly recommend amateurs to do the same, unless they have plenty of leisure, and in that case there is, no doubt, great pleasure and benefit in experimenting.

But first loves are strong, and so I returned from time to time to my wet plates. A few years ago I contrived a very portable and convenient box tent, which gives but little reason for complaint on the score of weight or bulk. It is suitable for plates up to seven by nine inches, and, when folded up for carriage, contains a water-tight bath, ebonite developing tray with plate glass bottom, and a stock of chemicals sufficient for a long day's work; yet it may be carried in one hand for a long distance, and only measures, when closed, fifteen and a half by twelve and a half by six and a half inches, while two or three minutes

are sufficient to erect it and put it in working order on its own tripod. I have taken many of my best wet-plate negatives with this tent. I confess that I prefer wet plates to dry wherever I have convenience for working them; and, wherever the view I wish to photograph is reasonably near to my head-quarters for the time being, I employ wet plates. I have, however, always the dry to fall back upon when the distance is considerable or the time for preparation limited, or where the employment of the wet process would interfere with the pleasure or liberty of any friend with whom I may be out for the day. These are the occasions on which the advantages of the dry plates show themselves, and many good pictures may be obtained by means of them when the wet process would be quite inadmissible.

As to the camera, I would only say that no one should think of working without the advantages of either a swing back or a swing front; and the motion of the back or front, or of the two combined, should be such as to give the means of adjusting the focus not only for different distances in front—such as a very near bit of foreground, or a tall spire, &c.—but for different distances to the one side or the other, as the side of a street or avenue, &c. Many good subjects will, indeed, present themselves, for taking which satisfactorily these are not in the least necessary; but, on the other hand, without such appliances many inviting subjects either cannot be taken at all, or taken at a great disadvantage, rendering it necessary to have some portion of the subject on which much of its interest and beauty depends either left out altogether, or quite destroyed for want of true focus. I also always carry a small spirit level; indeed, I have one fixed on the camera by a screw at one end, on which it pivots. This is most useful, not only in taking buildings, but in working on a hill side, where the eye is often quite at fault as to horizontal lines.

Thus much for the negative; and in anything I have to say as to printing from it I shall limit myself entirely to a few remarks on skies and cloud effects.

The sky is half the picture—sometimes, indeed, the "better half;" for the charm of the original of which the photograph is the transcript is often mainly in the sky and in the aerial perspective which it gives. Take a moorland view, for instance, with a pool of mossy water, and a few rocks and ferns and stunted furze for a foreground, and a bright sky with fleecy clouds overhead, stretching away till it meets the distant hills that bound the view. What a charm there often is in such a scene! and how beautiful the miniature representation of it as we see it on the screen of the camera! But print from a negative taken from such a scene, and how disappointing is the result! Wanting the cloud effects it is a mere caricature of the landscape it professes to portray; whereas if a suitable sky be skilfully printed in, the beauty of the original is restored, and the pleasurable emotions which it produced are re-awakened as we look on the faithful reproduction. Such a scene as I have here supposed is, indeed, more dependent on the sky for its effect than one presenting greater variety of form, and subject, and boldness of outline. But every landscape that includes a skyline is dependent more or less on cloud effects for its beauty; and if the sky be left in the print a dead blank, the picture is robbed of its charm, and photography is unjustly held responsible for a defect which ought to be charged to the want of taste in the photographer. Perhaps, however, with the professional the price which the photograph will bring in the market has something to do with the matter. Yet it is much to be regretted that anything should induce an artist to set before him any but the highest standard of excellence to strive after; and I believe it is a false policy in the end, for the best work will command the best price, and give the satisfaction of an honest endeavour after the highest attainable results.

(To be continued.)

PERSONAL TUITION IN CARBON PRINTING.

IN the recent discussion in our pages on the possibility of "picking up" the carbon process without specific tuition, it was, we think, generally agreed that lessons of some kind, oral or written, were imperatively necessary, and that where it was available, personal tuition was an advantage not to be rejected. The fact that in photography there have been hitherto but few apprenticeships, few professors and pupils—that, in fact, the majority of those practising the art, either for pleasure or profit, have "picked it up," aided by manuals, journals, and societies, with the occasional personal aid of some friendly practitioner—has naturally engendered in the minds of photographers generally a notion that all things pertaining to photography should be subject to like conditions. New processes or new methods and improvements have been introduced from time to time, and have been adopted without trouble. Something less than twenty years ago the alkaline gold toning solution was introduced to supersede the old hypo toning bath. The conditions were in many respects novel, but photographers mastered them by the aid the journals afforded. So with the abandonment of pyro, and the substitution of iron salts, for development. So with various dry processes. Hence it is not unnatural, when a new system of printing is introduced into photography, that those photographers disposed to try it should expect, after a little effort, to master it without tuition, picking it up as they had other novelties. But carbon printing is a change of such a radical kind, and for its successful commercial practice requiring such a revolution in the system of working that experience in silver printing, instead of being an aid, has, in many instances, been found an impediment to facility and success. Men of patience and skill have "picked up" the process, of course, without tuition, but as success depends much upon experience in methods of working, much time and patience are wasted in any unaided attempt so to "pick up" a mastery of the new method.

There cannot be a doubt that tuition by a capable practitioner very materially shortens the road to success; but it has so happened that just at the period when professional photographers are beginning to be keenly alive to the importance of carbon as removing the stigma of instability under which their art rests, the barrier, in the shape of a thirty-pound licence fee, stares them more prominently in the face, with the still more prohibitory, although not unnatural, condition that instructions will be given to licensees only. Many photographers aiming at straightforward fair dealing, recognizing in the thirty-pound charge for a licence only a legitimate remuneration for time and skill expended in working a process out, and placing it in a practical and working form before photo-

graphers, do not object to pay the fee itself, but for one serious misgiving. They are doubtful as to whether they shall be successful in working the process, about which an air of secrecy and exclusiveness has very unnecessarily been thrown of late. The payment of the licence fee being of course a preliminary to the receipt of lessons and the acquisition of knowledge, no certainty could be gained in advance. Our pages, it is true, have teemed of late with communications from gentlemen of skill who have been successful, and who, being licensees, are familiar with all the arcanæ supposed to be so carefully guarded; but still doubts have prevailed.

Tuition and practical demonstration easy of access, moderate in cost, and from a trustworthy teacher, were manifestly the wants of the day, in relation to carbon printing. And these wants may now readily be satisfied. The thoroughly trustworthy teacher is the first requisite. About his ability and experience there should be no doubt or question; and his ability should be avouched by his work. We believe that we hazard nothing in remarking that Mr. Higginson, of Southport, is the most successful carbon worker of the day. His praise is in all the studios where carbon is known. His work, of which we have seen much, is superb in its excellence; it is, indeed, literally faultless. Thus much we can speak from personal knowledge. Of the varied improvements he has introduced in the practice of carbon printing, of his personal skill, and the rapidity of his system, we have heard much from various visitors to his establishment. One enthusiastic Lambertyper, whom Mr. Higginson had redeemed from the Slough of Despond, declares that Mr. Higginson is as much in advance of Mons. Lambert, as the latter was in advance of all other carbon workers. Another visitor assures us that the statement was literally true that Mr. Higginson could produce a larger number of perfect double-printed chromotypes in the same time, than a skilled silver printer could produce ordinary albumenized prints. Many of our readers have doubtless seen the challenge to the best silver printer, issued some time ago by Mr. Higginson, and are familiar with his announcements that he is prepared to give lessons and demonstrations, in which he will show that carbon printing for ordinary small work in portrait studios is easier and more certain than silver printing. This announcement was deprived of the greater part of its general interest, however, by the limitation that these lessons and demonstrations were for licensees only. Instead of being able to acquire the assurance which such demonstrations would bring, as an inducement and encouragement to pay the requisite sum for a licence to practise, it was only attainable after the thirty pounds had been disbursed. We are happy to be able to announce, however, that this limitation will no longer exist. Mr. Higginson has resolved that his lessons and demonstrations shall be accessible to photographers generally, whether Lambertype licensees or not. The non-licensees, the Autotype licensees, and the Lambertype licensees, will in his lessons be placed on the same footing. For a moderate honorarium all will be taught every detail of every process. It rests, then, with the pupil as to what course he will take. Having acquired practical knowledge of the processes, and skill in working them, he can make his election as to which licence he will obtain. He may rest assured, apparently, that unless he is prepared to become defendant in a Chancery suit, some licence will be required. And if he be a reasonable man he will probably come to the conclusion that the high state of practical perfection to which the process has been brought is mainly due to the existence of a patent which has given some one a sufficient interest in cultivating the process, and overcoming those difficulties which few, without a special and pecuniary interest, would have had the time or patience to work out and overcome. The process, as the photographer may now acquire it, as compared with its crude idea in an unprotected and un-

cultivated state, is as a fair garden compared with a piece of common land or moor. And the money value or rental of the two would probably bear the same relation.

THE DISCUSSION ON THE NEGATIVE BATH.

In a letter on another page, Mr. Thomas calls attention to a somewhat important omission in the recent discussions at the Photographic Society in relation to defects of the silver bath. With the exception of Mr. York, no one taking part in the discussion brought examples of the defects which were spoken of in general terms as "spots" and "pinholes," as though these defects were always specific in character; whilst in point of fact, although similar, they vary, and it is probable that on careful examination each special cause will be followed by a distinct character of defect. We have an illustration of this in the illustrative negatives brought by Mr. York to the last meeting. Mr. York found, oddly enough, that a sulphate added directly to the bath did not produce the pinholes which were supposed to result from the presence of sulphate of silver. The negatives in question are now before us, and are quite free from pinholes; but they are characterized by another defect, to which Mr. York in his remarks referred as removal by the addition of nitrate of baryta. This defect consists in streaks and zigzag lines, or markings like a "watered" silk. And such streaks and markings were amongst the defects which Dr. Vogel found as, together with pinholes, amongst the results of sulphate of silver when he first proposed the use of nitrate of baryta as a remedy.

If all the forms of pinholes and other defects were produced direct by artificial means, and a careful examination made of their appearance and character, it is probable, we think, that they would be found sufficiently special to afford a future guide as to their source and origin.

MILITARY PHOTOGRAPHY.

From the *Army Estimates* we learn that a larger expenditure than usual will be made this year upon matters photographic. The field photographic equipment which will form part of any future army has now been completely organized by Captain Abney, R.E., F.R.S., who has had charge of the same, as also of the instruction of the officers and non-commissioned officers entrusted with photographic duties, during the past five years, at Chatham. Captain Abney, after having established both chemical and photographic schools of instruction at Chatham, now leaves that station, his term of staff service having expired, and proceeds to South Kensington, where he has been appointed Inspector of Science Schools.

Captain Abney is succeeded at Chatham by Lieut. Darwin, R.E., son of the well-known Dr. Darwin, and himself a gentleman who has already made his mark in science. Lieut. Darwin was entrusted with the care of the photographic operations at one of the Transit of Venus stations two years ago, and acquitted himself of the responsible duty in a most satisfactory manner. So far as photography is concerned, he is, we believe, one of Captain Abney's pupils, and consequently well fitted to carry on the work on which the latter has been for some time occupied.

The field photographic equipment, as organized at Chatham, is now a very complete affair. A waggon fitted with every convenience, and carrying the necessary apparatus and chemicals, forms the head-quarters of the photographic staff, who are, however, provided with the means of working when this comfortable conveyance cannot be resorted to. The last, and by no means the least, important addition that has been made to the equipment is, we are glad to hear, Warnerke's negative tissue, and that gentleman's ingenious dark slide, which will be invaluable for reconnaissance work. A better testimony, we think, of the practical value of this material could hardly be afforded, and we heartily congratulate the hard-working experimentalist on his deserved success.

AN EMULSION PROCESS.

BY CAPT. ABNEY, F.R.S.

It may not be uninteresting to some of your readers that I should give an account of a method of making a rapid emulsion, and which also possesses unusual delicacy. I was led to it in prosecuting researches on the photography of the ultra-red end of the spectrum, and have found it sensitive to these rays, though owing to the present want of sunshine I have been unable to arrive at any definite idea of its value compared with other emulsions containing organic salts that I have previously used. My friend Mr. H. Berkeley has worked with it, and reports favourably of it; and Mr. Warnerke, to whom I gave the formula, I believe has found it efficient.

The following is the mode of preparation:—Sixteen grains of ordinary cotton (*not high temperature cotton*) are dissolved in six drachms of ether and four drachms of alcohol, both being as far as possible free from water. In each ounce of collodion twenty grains of zinc bromide are dissolved, and fourteen drops of strong nitric acid also added. For each ounce of the above, one grain of dried albumen is taken and dissolved in a little water, to which a little ammonia has been added to aid solution. The collodion is poured into a glass jar, and the albumen added little by little—stirring the whole time. This forms a sort of emulsion of albumen in the collodion.

Mr. Berkeley proceeds in a somewhat different manner. He adds the cotton to the ether, then adds the albumen, and finally adds the amount of zinc bromide in the necessary alcohol. This is a very effective method of proceeding, but the former answers as well.

Enough silver nitrate is then dissolved in the smallest quantity of water, and alcohol added to it, and the emulsion formed in the usual manner. The amount of silver nitrate to be added is fixed by the fact that there *should not be less than two grains in excess of that necessary to convert the whole of the soluble bromide into silver bromide, and the albumen into silver albuminate*. This can only be arrived at by calculation checked by a trial of the amount necessary for the conversion of the albumen—practically, about thirty-six grains will be found sufficient for the above amount of bromide and albumen.

The emulsion is next poured into a dish and allowed to set firmly. This I encourage by moving the liquid in the dish by means of a stirring rod. When the mass is capable of being broken up into small coherent lumps of the consistency of thick jelly, the washing commences. This I effect first in the dish by covering the pellicle with distilled water, and allowing it to soak for about five or six minutes. It is then transferred to a glass beaker, and washed with constant changes of water for about two hours. At the expiration of that time the washings should only give a very slight milkiness when tested for silver with hydrochloric acid. I consider the washing complete when the wash water to which the acid has been added appears of a turbidity equal to that shown by dissolving one-sixth of a grain of sodium chloride in four ounces of water, and then adding silver in water to it. When in this state the pellicle is dried in a water oven, taking care previously to get rid of all excess of water by squeezing it between folds of pure blotting-paper. This operation takes about three-quarters of an hour, and to test when the pellicle is sufficiently desiccated it is as well now and then to take a small piece of the emulsion from the oven, press it on blotting-paper; when no stain of moisture is shown, I consider it sufficiently dried. I may remark, that in my experience excessive desiccation of any pellicle seems to destroy the qualities of the resulting emulsion.

The pellicle is next dissolved in equal parts of ether and alcohol, allowing eight grains of cotton for each ounce of the combined solvents. This may not be sufficient, but I consider it better to add too little than too much of them at first. The alcohol may be of strength equal to .812, and the ether of .720; both of them may be methylated, the

for great sensitiveness I rather incline to the pure solvents. On coating a plate with this emulsion, and after drying, if the film be examined against a gas-flame, the colour will be seen to be very remarkable. The flame will appear of a greenish-blue tint, not in the least white, but rather of the colour that would be observed were the glass coated with a fine film of silver. The difference between this emulsion and the ordinary kind is very marked; with a film of the latter the flame appears of a red orange.

The exposure necessary to give the plates is very small, even when compared with a wet plate. I believe them to be twice as rapid as plates prepared by the ordinary wet process, when exposed under the same conditions. The blue colour of the film indicates the cause of this—the particles of the sensitive salts are in a much finer state of division than is usually to be met with. A microscope reveals this fact most unmistakably.

There are several ways of developing these plates. The ordinary strong alkaline developer, with a double dose of bromide, is most effective, whilst pyrogallio acid alone will give a feeble image, capable of being given intensity by the ordinary method. A gelatino-iron developer is also effective, as is also pyrogallio acid with acidified silver nitrate.

I should be glad to hear of any of your correspondents who may try this process giving me the results of their observations. I have found it a cleaner and smoother emulsion than any I have made, and certainly much more rapid. The fault, if it have any, is, that it is apt to give negatives slightly wanting in density; but this can be corrected by using the intensifier I brought before the Photographic Society last meeting, or by substituting hydrochloric acid for a quarter of the nitric acid used in preparing the emulsion.

ON PLATINOTYPE.

BY THOMAS RODGER.*

GENTLEMEN,—I have the honour this evening of drawing the attention of this Society to a very beautiful process of printing from photographic negatives, termed platinotype. The author of this process, Mr. Willis, was present at your last meeting, and it would have been highly satisfactory that circumstances had favoured his bringing this subject before you himself. As it is, I will endeavour to describe briefly the chemical principles on which this process is based, and then give you a practical demonstration of the *modus operandi*, as far as is possible.

This process, I need scarcely tell you, has been repeatedly and very lucidly described in our photographic journals, as well as in other periodicals, and particularly so by Mr. J. Traill Taylor in the *Science Review*. But it seems to me that it has not received that amount of attention which it deserves from the great body of photographers. The great simplicity of the few operations requisite, and the absence of that capricious character which attends several other processes, apart from the undoubted and absolute permanency of the result obtained, ought to gain the attention of a large majority of the brethren in our art.

Without presuming to make a comparison between results obtained by other methods and those of this process, I may be allowed to say a few words. In the ordinary application of this process to the printing from negatives of all sizes, and in which it is not intended to subject the prints obtained to painting or other art finishing, I am aware that it has generally been asserted by the profession, and this with some reason, that the colour of the prints which they had seen was too cold to satisfy the general taste. Now, from the small amount of experience which I have had in this process, and from what I have seen produced by others with more, I feel confident in saying that there is little fear of getting a

wide range in tone quite sufficient to satisfy in this respect.

In our much-loved process with silver in its several conditions forming the picture, we have found it too facile in every respect—so much so, that I fear that at the very best, pictures formed of silver in metallic form, or in other combinations, cannot fail to be very prone, both to internal as well as to external influence. In the case of pictures formed of platinum, if we succeed in obtaining the beauty of the silver picture (and this I think quite possible), we have a basis for our productions quite beyond those influences in the highest degree. Again, there is a very important branch of the art which, for years past, has been of much consequence to the professional photographer. I allude to the artistic finishing in oil and water colour, &c. Now, I hardly think I need remark that the application of pigment in any form has been found, from various causes, to do other than hasten the destruction of the photographic image which formed the guide of operation. Now, in a picture formed of platinum, we have a deposit of the pure metal in the form of what is generally termed platinum black, forming the image in direct contact with a surface, and without being enclosed in any film, and, consequently, fit to be loaded to any amount with colour without danger of peeling off or chemical change. This has always seemed to be a desideratum connected with the class of work referred to, and this process offers every facility to fill the void.

I shall now endeavour to give you a short description of the rationale of this process. Mr. Willis, in a series of experiments to find the best reducing agent of platinum, and without any special photographic aim, found that oxalate of iron—a yellow, and in most menstus an insoluble powder—was soluble in a warm solution of oxalate of potash, and that it in this condition acted most energetically as a reducing agent on soluble salts of platinum. Mr. J. Traill Taylor in his article referred to, gives such a clear and short description of the chemical changes involved in this process that I cannot do better than quote a few of his remarks with the least possible modifications.

Mr. Willis, therefore, having discovered that as a solution of ferrous oxalate in potassic oxalate was so perfect a reducing agent of platinum, conceived the idea that as ferrous oxalate can be produced by the action of light on ferric oxalate, it ought to follow that paper or other media which has received a wash of platinum will undergo reduction in proportion to the action of the light. In the practical application of this process, pictures of fine quality are obtained in about one-fifth the time of exposure requisite in ordinary silver printing. When the pictures are taken from the printing frame they are feebly, though distinctly, visible, although up to this stage the platinum has not taken any part in the performance. The visible picture is wholly composed of ferrous oxalate, and it would have been equally visible had no platinum been present. The picture is now drawn over a warm solution of oxalate of potash, and instantly the image formed of metallic platinum becomes strong and rich, and of a warm black tone. As far as mere permanence is concerned, the picture may now be considered finished. The developing action of the oxalate of potash will be readily understood from the following considerations:—Bearing in mind the axiom that no chemical action can take place unless one of the substances be in solution, observe that when the picture is removed from the printing frame the two substances are solid; so to speak, apart, ferrous oxalate and the platinum salt, and hence the former body has not had an opportunity of acting upon the latter, both are side by side, and in the most favourable condition for one to act upon the other, but it is held in check. The question now arises, what will relieve it so that it may reduce the platinum so conveniently placed for this purpose? This ferrous oxalate produced by the action of light is not soluble in water, but it is so in a solution of oxalate of

* Read before the Edinburgh Photographic Society.

potash. No sooner, therefore, is the picture brought into contact with a solution of this salt, than the exposed parts consisting of ferrous oxalate are dissolved, and immediately exert their reducing action on the neighbouring particles of platinum, which thus are made to form the picture. It must be remembered, however, that the paper or surface was charged with ferric oxalate in order to secure sensitiveness to light, and that it is desirable that this should be removed. To effect this, it is only requisite to subject the print for a few minutes to a weak solution of oxalic acid. This renders the whites very pure.

(To be continued.)

Correspondence.

AN OLD BATH WHICH DID NOT GET OUT OF ORDER.

DEAR SIR,—I notice some interest is excited in the diseases of the negative bath just now. I believe the bath troubles are mostly traceable to the person of the operator. If Mr. Spiller or anyone else would care to examine the enclosed, he may perchance find out something, though possibly it will be more of a negative nature than anything directly informative.

The mess enclosed is the filtrated deposit found in a negative bath, originally measuring about three gallons. It had never been strengthened; it had never been filtered; it was in daily use; never had any rest; never sunned; never covered up to keep in the ether and alcohol, or to keep out the dust, except once a week, when the dark room was cleaned after thousands of half-plates and other larger negatives had been made in it—the bath got so low that it would not cover the breadth of a half plate, yet the last negative was *perfect*, no pinholes, no stains or streaks, no intensification necessary, yet fully soft. I suppose in ordinary practice it would be expected that the bath should have *broken down*, but this it never did. I have at this moment a bath similarly used, and in as positively a filthy state—which anyone may see—yet though my negatives should be full of pinholes and stains, I find them quite free from such defects.

But if I filtered it, and so upset it, my experience would lead me to expect *hard negatives* at once, and it would soon break down altogether. I will not bother you with my theory, but if anyone cares to examine the enclosed I would very much like to know his opinion as to its nature.—Faithfully yours,

PORTOBELLO.

[As Mr. Spiller was engaged in examination of similar deposits when we received the above letter, we placed the filtrate above alluded to in his hands, and he was good enough to furnish the following report.—ED.] :—

MY DEAR SIR,—I found an opportunity to-day of testing the silver deposit from negative bath which you sent me a few days since. It consists principally of *carbonate* of silver, with small quantities of sulphate, bromide, iodide, and reduced metallic silver. It is quite devoid of detonating properties, and contains no cyanide.

Your re-publication of Dr. Vogel's old communication is very interesting, and shows how fully he had gone over the same ground. With kind regards, I remain yours very truly,

JOHN SPILLER.

2, St. Mary's Road, Canonbury, N., March 28th.

NORTHERN PHOTOGRAPHIC NOTES.

SIR.—The Edinburgh Society's meeting of last Wednesday was a very enjoyable one. Mr. Rodger, of St. Andrew's, treated the Society to demonstrations by Willis's platinum process. I am afraid the Albion Albumenizing Company will not be able to do much with it, even although Mr. Rodger, and others of influence, should praise it. It is not a perfect process; it is not certainly a permanent process; and, owing to the cold colour of the prints, its use is limited to a very great extent. Francis Miles, and a

series of comic sketches published by Poulton, are printed by this process, but these have the doubtful element—*via*, hypo.—and if hypo. remains to any extent in the print, it is open to as much distrust as silver.

Herr Kareline, of Nijni-Novgorod, hopes to make a fortune by teaching us how to produce groups and genre pictures by means of some marvellous contrivance producing depth of focus to a great extent, and—mark this—without the aperture being diminished. The pictures which appeared at the Edinburgh Photographic Exhibition are referred to in a letter from Herr Kareline read at the Society's meeting last week. He says :—"These are my ordinary productions, and not exceptional pictures; they are not produced by any known method; they are not double printed, not touched up on negative or print—indeed, it is a secret of my own." We may expect to receive, in a few days, a proposal to divulge, in a multiplicity of paragraphs, and for a handful of roubles—after the style of C. Klary—the wonderful system which has "seduced and enraptured" the great and small, rich and poor, photographers of Edinburgh.

Mr. Paton, of Greenock, was at the meeting, with his clever pictures after Kareline. He thinks the secret is now no secret, and explained his mode of procedure; but Paton the prophet was not in a far country. What a scandal it would be if a Greenock-body were to teach the wise men of the East some new thing!

Edinburgh photographic business is in a poor way just now. Here is an ominous sign: a well-known photographer advertises to take a negative and supply a print for one shilling! I would as soon go off, in a suit of solemn black, to deliver moral pocket handkerchiefs amongst the Red Indians, or stay at home to sell wooden nutmegs to the dispeptic mothers of Midlothian; it would be ill to tell which of all would be the most disreputable. A Glasgow photographer, long ago, took a carte and supplied a proof for a shilling. He made a reputation, and money also—pound notes. He made a journey across the Atlantic with his pockets full of *home made* pound notes, and a lady—not his wife—hanging on his arm. The authorities brought him back, and had him tried and found guilty of taking a negative and producing a print for one shilling—at least, this was the verdict of a photographic jury, although tendering forged notes was the most serious count, for which he got penal servitude. Mr. John Nicol, Doctor of Philosophy, once tried to write up "penny photographs"; I would like to say something on them also, but at present I cannot afford to be sarcastic on anything lower than taking a negative and supplying a print for a shilling.

Mr. Samuel Fry well knows that as long as carbon printing was in embryo it was free to everybody, and sluggishness, not progress, was the watchword. Those who have spent from twenty to thirty thousand pounds are more likely to have aided than hindered the progress of the art. Those who have added their quota of money as well as brains have in a couple of years made chromotypy a commercial success.

To say that "the Autotype Company have been hindering and hurting the progress of the art" is a gross libel. To say that "the Company's present action will prevent experimental trial, and that it will cut off carbon work from a large number of photographers," goes for nothing, in the face of "only thirty issuing their work in this way." Messrs. Urie, Fry, and Company, who talk about the patents limiting and hurting the progress of the art of pigment printing, argue on false premises, and the sooner they see it the better for themselves.

Let us end this dispute about the patent rights by recognizing them, for they are not grievous burdens, but all the other way. Mr. C. J. Witcomb's example should teach us all to be more liberal-minded. I intend telling a thing or two myself next time I write to you.—Yours truly,

JO. VANNIA.

M. BOISSONNAS' SPECIMENS.

DEAR SIR,—It may interest some of your readers who were not present at the meeting of the Photographic Society on Tuesday last, to know that the albums of instantaneous and other photographs exhibited by Mons. Boissonnas, of Geneva, are in my possession, and that I shall be very happy to show them to any one who feels interested in them, and who will favour me with a call.—Very truly yours,

JAMES A. SKEWES.

9, Grafton Road, West Kensington (Addison Road Station).

DISCUSSIONS AT THE PHOTOGRAPHIC SOCIETY.

SIR,—Will you permit me to suggest that, by way of illustrating the subject under discussion at the meetings of the Photographic Society, some of our friends would perform an act of kindness, and at the same time help to elucidate the matter, if they would exhibit some specimen negatives showing the character of the defects now brought before the notice of the Society? There could then be no misunderstanding regarding these plague spots. There are pinholes and pinholes, spots and spots, comets and comets; it would be well to have these diseases properly classified for the purpose of easy recognition; or, in speaking of pinholes, one person may mean one thing, and another something quite different.—I am, yours, &c., R. W. THOMAS.

Proceedings of Societies.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

An ordinary meeting of this Society was held on the 5th inst., the chair being occupied at first by V. E. FOXLEY, and afterwards by the Rev. F. F. SATHAM, M.A., President.

It was intimated that in consideration of no paper having been previously prepared for the meeting, Mr. Edward Danmore had kindly written a short one on "Drawbacks," since he had arrived at the meeting. This was accordingly read (see page 172).

A conversational discussion ensued, during which

Mr. WARNERKE said that although reticulation of collodion was generally attributed to water, it was owing, in most cases, to the nature of the pyroxyline.

Mr. W. M. AVES found that the best means of cleaning negatives which had become discoloured in printing was to rub them with turpentine on a pad of wool.

Mr. FOXLEY, with reference to a remark that had been made concerning carbonate of ammonia in the printing bath, observed that Mr. Spiller had recommended it as a solvent for the albuminate of silver that was formed.

After a desultory conversation, the thanks of the meeting were voted to Mr. Danmore.

Mr. WARNERKE exhibited a number of negatives and specimens showing the action of bromide of copper as an intensifying agent, and showed the method of applying it. He further exhibited a plate box for holding wet negatives, and the triangle of a camera-stand which had been constructed by Mr. Lane. After a vote of thanks to Mr. Warnerke the proceedings terminated.

EDINBURGH PHOTOGRAPHIC SOCIETY.

The sixth ordinary meeting of the session was held in 5, St. Andrew Square, on the evening of Wednesday, the 4th inst.

The chair was occupied by the President, Mr. Lussell, and the number of members present was unusually large.

The minutes of the previous meeting were read and approved, and the following gentlemen were admitted ordinary members:—Messrs. Charles Philip, John Macmahon, Daniel Macfarlane, James Muir, James Dickson, and James Hay.

Mr. RODGER, of St. Andrew's, read an interesting paper on the "Platotype Process" (see page 176), and illustrated it by a number of successful experiments, which conveyed a clear idea of various reactions involved. Especially interesting were the experiments by which the simplicity of the process, the rapidity with which the paper was prepared, and the great sensitiveness of the preparation were shown. Some idea of the latter may be gathered from the fact that two prints were obtained from negatives by an exposure of under two minutes to the light, given out by the combustion of a double strand of magnesium wire.

The President said that the Society was much indebted to Mr. Rodger for the clear description he had given of the interesting process, and especially for the highly instructive experiments which must have entailed so much trouble to him. From the lucid way in which the subject had been treated, there could be no question either of the success or value of the process.

Mr. TURNER congratulated Mr. Rodger on the successful demonstration of what he considered the best process yet devised for many purposes, and especially for coloured work, the texture being just the very thing required in that branch of art. He had experimented a good deal with the process when it was first introduced, and he had no doubt that prints in platinum black were quite as permanent as those in carbon. They were not affected by either nitric, sulphuric, or hydrochloric acids used singly, although of course they yielded readily to the nitro-hydrochloric; and he found also that a strong solution of hyposulphite of soda materially changed the colour of the deposit, and therefore supposed that something like a platinum hyposulphite might be formed.

Mr. BASHFORD had not previously given the process much consideration, and therefore until to-night knew very little about it. He thanked Mr. Rodger very much for the beautiful demonstration and lucid explanation, and was quite satisfied that from them he had learned enough to enable him to succeed on a first trial. The only difficulty that occurred to him was that of ascertaining exactly the proper exposure, as from the fact that the development was almost instantaneous, and the difficulty of in any way reducing a too dark image, he presumed that there could be but little latitude in the time of exposure.

Mr. TURNBULL was very much pleased with the paper and experiments, and was quite sure that from what he had just seen he could at once do good work in platino-types. It was so simple and so satisfactory that, in all probability, carbon printing would soon be a thing of the past.

In reply to a question from Mr. Norman Macbeth, Mr. RODGER said that from his experience of the process he had no doubt that the actual cost of prints in platino-type was considerably less than that of prints in silver; and in answer to Mr. Bashford, he said that it was quite true that a platinum print could not be easily toned down or darkened, and, in consequence, the exposure must be properly timed; but neither he nor his assistant found any difficulty in hitting the proper time when the actinometer was used.

A number of fine specimens were then handed round for inspection—some by Mr. Rodger himself, some by the Albion Albumenising Company, and some by Mr. Griggs, of Blackpool. All were very beautiful, the latter especially so, as they were not only most charming subjects, but, by a method of his own, just sufficiently glazed to give the generally admired transparency not often seen in prints on plain paper.

There were also shown some prints on rough crayon paper by Mr. Willis, the inventor of the process, from paintings or water colour drawings, regarding which Mr. NORMAN MACBETH said that he had never seen anything finer. They came nearer to the pure white and black of an engraving than copies by any other process, and would, he thought, compete very closely with the productions of Messrs. Goupil and Co., now so popular.

Mr. HUNTER, of Hawick, also exhibited a number of very good carte portraits printed in platino-type, and said that he had only given the process one trial, and those were the results. It was certainly the simplest process he had had anything to do with.

The Corresponding Secretary then read a letter from Mr. Kareline, of Nijni-Novgorod, which mainly referred to the criticisms that had been published on his works, especially the picture to which was awarded the gold medal at the late Exhibition. Mr. Kareline wrote to the effect that all his pictures sent to the Exhibition were printed from single negatives taken direct, and were untouched prints from untouched negatives; that with trifling exceptions they were the portraits and groups taken in the ordinary course of business, with no more time devoted to them than is generally given when other sitters are waiting. Mr. Kareline has evidently solved the problem of how, by a small stop or otherwise, in combination with a short exposure, to get objects that are in various planes in equally good focus, and for this secret he has been offered considerably over fifteen hundred pounds; but he wants nearly five thousand, that he may be able to devote himself more thoroughly to photography as an art.

Mr. PARON, of Greenock, who, along with the Secretary of the Glasgow Photographic Association, had come through to attend the meeting, laid on the table a number of cabinet pictures in

imitation of Kareline's style, and briefly explained the method of lighting employed. The principal light was admitted through an ordinary window in the wall of the studio, and the shadows softened by a secondary light coming from a considerable distance in front. Under ordinary circumstances the detail in the white curtains would be lost from the large amount of light coming through the window, but this was obviated by lining them with an opaque substance, the front light only being allowed to act on them.

Mr. TUNNY, while admiring the pictures shown by Mr. Paton, and admitting that they bore a close resemblance to those of Mr. Kareline, still held to his original opinion that the window was not the source of light, that it was in fact a property window, and that the principal light came from above it, and the secondary from a long way in front, or from reflectors.

Dr. THOMSON said they were greatly obliged to Mr. Paton for giving them an opportunity of seeing his pictures, and for the description of the condition under which they were taken, as they had gone far to illustrate the method adopted by Mr. Kareline. He hoped others would soon follow in the way led by Mr. Paton, and that we should soon have many able to produce work equal to that of the successful Russian.

A number of fine carbon enlargements by Messrs. T. Annan and Co., of Glasgow, in both single and double transfer, were then brought to the notice of the members, and elicited much admiration, "The Broken Toe," by Mr. Diston, of Leven, in various sizes, being exceptionally good—much better, in fact, than a print from the original negative.

The SECRETARY next read a communication from the Glasgow Photographic Association with reference to a possible application for an extension of the patent granted to Mr. Swan, which expires next year, and requesting the co-operation of the Society in opposing such an application.

Mr. ROBERTSON (the Secretary) briefly explained the reasons that had induced him to send out the circulars, and

Dr. JOHN NICOL said that while anxious to fraternize to the fullest extent with their Glasgow friends, he had a doubt as to the propriety of entertaining the question now brought before them. One of the fundamental principles of the Society had been the determination to steer clear of the commercial element, and he thought any action in regard to patents would be an unwise departure from that principle.

It was ultimately agreed, on the motion of Mr. Pringle, seconded by Mr. Dobbie, to remit the matter to the council to bring up a report on the subject.

In accordance with a provision in the circular, a number of pictures from foreign exhibitors, that had been mounted and framed by the committee, were disposed of to the highest bidder, and brought fairly good prices, upwards of fourteen pounds being realised.

Votes of thanks were then given to Messrs. Rodger, Robertson, and Paton, and the meeting was adjourned, several items on the billet being postponed in consequence of the lateness of the hour.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE ordinary monthly meeting of this Society was held at the usual place of meeting, the Museum, Queen's Road, Bristol, on Wednesday, the 4th inst., Dr. THOMPSON in the chair.

The minutes of the previous meeting having been read by the Secretary, and confirmed,

The SECRETARY read a communication received from the Glasgow Photographic Association, asking for the co-operation of the Bristol and West of England Association in trying to prevent the renewal of the Swan carbon patent.

A general discussion ensued, when the following reply to the Glasgow Society was decided on:—

"Under the existing patent good and reliable tissue is manufactured. The non-renewal of this patent would chiefly affect professional photographers, and would not increase the scope for fresh discoveries proportionately with the sacrifice that would necessarily accrue to the present holders of the patent; for, without any discourtesy, it is generally admitted as incontrovertible that few, if any, discoveries of importance have emanated from the professional community—no doubt attributable to the want of time for research, and other causes. Also, looking at the probable manufacture of inferior tissues, this Association is of opinion that the renewal of the present patent (all requisite conditions being fulfilled) should not be opposed."

Mr. T. DAVY, of Bristol, was then elected an ordinary member of the Association. The Easter holidays having very

much interfered with the attendance of members, the meeting was adjourned at an early hour, Dr. Thompson's paper being postponed till the next meeting.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

THE usual fortnightly meeting of this Association was held on the 28th ult., in the rooms of the Religious Institution, Buchanan Street, Mr. URIN occupying the chair.

The minutes of the previous meeting having been read and adopted, and the correspondence read,

Mr. JOHN PARKER read his paper on "Landscape Photography" (see page 173), and exhibited a large number of specimens of his work, described his tent (which he had brought with him), and his *modus operandi* generally.

The paper was listened to with great attention, and the members were unanimous in considering his pictures beautiful specimens of the art, and his field tent an exceedingly simple, portable, and efficient one.

Mr. GILFILLAN suggested that Mr. Parker should lead one of his negatives to the Association, so that prints might be got therefrom.

Mr. MACPHERSON considered Mr. Gilfillan's suggestion a good one, and suggested that the negative be given to Mr. Stuart to print copies from.

Mr. TANNHILL thought that in the proper printing and toning lay a good deal of the beauty of Mr. Parker's specimens, and considered that many portrait photographers would be quite unable to produce such beautiful results from his negatives as he could himself; he would, therefore, suggest that the printing be left to Mr. Parker. That gentleman, he thought, had given a good lesson to many professional landscape photographers as regarded the production of views with cloud effects. Many of the latter gentlemen's work, as Mr. Parker had pointed out, were almost spoiled for lack of cloud effects.

The CHAIRMAN thought it too much to ask Mr. Parker to give both negatives and prints, and considered it would be better to pay one of their professional brethren who did something in landscape photography. The paper he considered the best that had yet been read before the Association. Of the specimens he could not speak too highly, their aerial perspective surpassing anything he had hitherto seen, while they were also extremely clear and sharp all over. The cloud effects were admirable and well-chosen; in that alone Mr. Parker had shown his artistic talent.

Mr. DODDS asked how the pictures in the frames were mounted—were they attached to the glass?

Mr. PARKER explained that some of them were attached by a thin, transparent gelatine. They were the first he had tried that way, and a bell here and there was to be seen; but he was now able to obtain them perfectly free from that defect. The mounting of the prints in the manner described was a good idea, he thought, giving them greater brilliancy than could be got otherwise.

The committee on carbon patents submitted a circular which they had got printed and circulated. This was read, and members expressed their approval of this part of the committee's work.

Mr. JOHNSTON made a few remarks regarding his bromide emulsion process, and exhibited a few negatives and transparencies taken from it.

The meeting was brought to a close by a vote of thanks to the Chairman.

FRENCH PHOTOGRAPHIC SOCIETY.

A MEETING of this Society was held on the 2nd March, M. PELLEGOT in the chair.

The SECRETARY called attention to the forthcoming photographic exhibition at Amsterdam, and announced to the members that applications for space must be made before 15th July.

A letter was read from Mr. Sahler in which he announced the fact that he was occupied in the elaboration of a photo-chromic process of a purely chemical and physical character.

M. PERROT DE CHAUMEUX gave an abstract of the foreign journals.

Mr. BADEN PRITCHARD's paper on reticulation in carbon tissue was brought before the Society.

M. FRANCK DE VILLECHOLLE read the report of the Commission appointed to examine the *laveuse hydraulique*, or washing apparatus of M. Collet. The verdict of the Commission was that the apparatus was a very useful one, and capable of rendering good service to the photographer; some defects, however, were pointed out.

M. FRANCK DE VILLECHOLLE gave his opinion of a sample of

carbon tissue from the manufactory of M. A. Braun. He said the material in question was remarkably fine and soluble, and submitted some proofs upon glass. He was glad to see that several firms were now engaged in the manufacture of carbon tissue, as in this way progress was sure to be made.

M. LIEBERT said the Braun tissue could be favourably compared with that from the Autotype Company, of which he generally made use.

M. HARRISON, while confirming the above opinions, said the tissue was apt to become brittle.

M. CHARDON bore testimony as to the good quality of the tissue made by M. Monckhoven.

M. FRANCK DE VILLEHOLLE announced that the Syndicate of Photographers, which occupies itself with the art from an industrial point of view, as the French Photographic Society cherishes the scientific aspect, had resolved in future to devote a portion of its time to the consideration of photographic patents.

M. DAVANNE remarked that the exercise of such a supervision as this could not but be beneficial to photographers, by looking after their interests.

M. FLEURY HERMAGIS submitted a model of a lens-cap, called the guillotine cap.

M. DARLOT called attention to the fact that he had submitted a somewhat similar instrument some time ago.

M. GILLOT submitted a number of photographs in half-tone produced in the printing press; they were, however, not taken from nature, but M. Gillot expressed a conviction that in a little while he should be able so far to improve the process as to render negatives taken direct from nature available in such work.

The Society thanked M. Gillot for his presentation.

The proceedings then terminated.

Talk in the Studio.

FIRE AT A PHOTOGRAPHER'S.—On the morning of the 29th ult. the flock works of Mr. Archd. Robertson, photographer, Dumbarton and Glasgow, secretary of the Glasgow Photographic Society, were almost totally destroyed by fire. The whole place is a total wreck. The machinery, both for the manufacture of flocks, wadding, and the making of bolts and rivets, is almost totally destroyed. The damage is about £2,000. The place was not insured. The origin of the fire is at present unknown.—*Glasgow Herald*.

MISAPPLIED PHOTOGRAPHY.—At the Birmingham Police Court on Tuesday, Alfred John Grattidge, photographic artist, pleaded guilty to circulating indecent literature, and was sentenced to twelve months' hard labour, in addition to a fine of £5. Last week a large number of photographs, songs, and books, including several copies of the "Fruits of Philosophy," found upon the premises of the prisoner, were ordered to be destroyed. The learned Recorder expressed a hope that the Watch Committee would reward Detective-Sergeant Black for the ability he had displayed in catching the prisoner and bringing him to justice. The prosecution was conducted by the Society for the Prevention of Vice.—*Daily News*.

PHOTOGRAPHS TRANSMITTED BY TELEGRAPH.—If there be nothing new under the sun, there are at least many things that strike one in a novel light. To wit, when the old philosopher illustrated the law of the gravitation of the earth by bag, clay, stick, and nut, he little thought he was paving the way for cocoa-nut—"three shillings a penny!" And, assuredly, the early inventors and adapters of the electric telegraph never imagined that photographs would be transmitted by the wire of electricity. Though photography is within our departments, we should not enlarge upon this point were it not for the fact that science is the great parent of toys. The original character of the picture has to be slightly altered, and the paper to be chemically prepared, and visible marks result where points in the electric circuit come into contact with the paper. Tinfoil has been used in experiments already successfully conducted, and the photographs have been reduced to lines.—*Stationer*.

To Correspondents.

D. WALKER, Duffield.—We will make enquiry, and see to cause and remedy, if possible, of the irregularity. Your specimens are very interesting, and the portrait by no means badly lighted. The lens you mark No. 2 will probably suit your purpose best.

INSTANTER.—The rapid rectilinear is, we believe, quicker than the triple lens of the same maker.

T. J. P.—With a brilliant negative and sufficiently deep printing almost any toning bath will give similar tones. The lime toning bath answers well for producing such tones. Take two grains of chloride of gold, one grain of chloride of lime, and twelve ounces of water. Mix, and allow to stand forty-eight hours. But remember that a weak negative, which only permits light printing, will not yield deep tones with any bath.

YORK.—We do not know of any remedy for greasy mounts except discarding them and obtaining others. The addition of a little ammonia to your adhesive material may assist you.

NORTHUMBRLAND.—Yellow spots in the finished print arise at times from a variety of causes, such as defects in the albumenized paper, the mounting material being acid, defective cards, the presence of dust containing chemicals, &c; but in the example sent, each spot has the appearance of distinctly imperfect fixation, which might arise from a multitude of small air-bells forming on the print when it was immersed in the fixing bath, and so preventing the proper action of the hypo. This would produce small spots of imperfect fixation, which would not show until the prints were in the washing water, or, still more frequently, not until just after mounting. 2. White is the best colour for securing good reflecting action in a reflecting screen. Grey may be used, but it will reflect less light. The best mode of avoiding the strong reflection of light in the eye is to turn the eyes somewhat away from the reflector.

DUST.—The nature of the powder to be employed depends entirely on the purpose to which the process is employed. If for producing enamels, vitreous colours must be used; if for reproducing negatives, plumbago is generally used; if for producing pictures, then the colour must depend much on the aim and taste of the artist. Carbon is frequently used in the shape of ivory black; sepia, umber, and other powder colours are available.

A WOULD-BE RETOUCHER.—If our correspondent had been an experienced retoucher, he would readily have seen the use of the pencil of lead, which is very valuable in securing light, delicate touches difficult to produce with the ordinary blacklead pencil. But if it were a "sell," as our correspondent suggests, he is quite mistaken in supposing that it should in any way devolve upon us to investigate and expose it.

DEVELOPER.—The best strength for a developer depends upon various conditions, such as the kind of work, the kind of light, the condition of the other chemicals, and the mode of working. The formula you quote, containing one ounce of saturated solution and thirty ounces of water, would give a nine-grain developer, which, for landscape work, would work, under ordinary circumstances, very satisfactorily. For portraiture we should, as a rule, prefer a fifteen-grain solution. A solution containing from thirty to fifty grains per ounce we should regard as a very strong developer, too strong for ordinary use. A saturated solution of protosulphate of iron (FeO, SO₄ + 7Aq) consists of six ounces of the salt in ten ounces of water at 62° Fah. This on the authority of "Storer's Dictionary of Solubilities," the authority on such points. The other writer you quote has made an error. Forms of protosulphate of iron exist containing smaller proportions of water of crystallization, and these are much less soluble. That to which we refer is the ordinary commercial article.

A WOULD-BE EXHIBITOR.—The nominal time for applying for space at Paris is passed; but if you apply at once, we have no doubt of your success in obtaining space still. But the sooner such applications are made the better, as having all the applications before them materially aids the authorities in allotting their general space, and making generally satisfactory arrangements.

LEGATRE.—You are right in congratulating yourself on the fact that you, in common with photographers generally, are the heirs and legatees of the pioneers of the art. But you are in error in some points. The originators of photography patented their processes. M. Daguerre, although he received a pension from the French Government for the free publication of his discovery, patented it in this country, and the patent was purchased and worked by Beard; much piracy and much litigation being carried on in the early days. Mr. Fox Talbot also patented his processes. The collodion process, although properly enough associated with the name of Archer, was, in fact, the combined work of many persons, and could not very easily have been patented by one. Mr. Archer did patent a much smaller thing in a mode of transferring the collodion film by means of gutta-percha. The mode in which a patent becomes an advantage to the public is two-fold: in the first place, it gives the patentee a beneficial interest, which renders it profitable for him to work his process out to a practical success, which, as this often involves the expenditure of much time and money, would not have been worth while for anyone to do without the chance of being reimbursed which a patent secures; and in the next place, a patent secures publicity, and is opposed to the secrecy which some inventors preserve. As a rule, those object most loudly to patents who have never originated anything themselves.

CARBON WORKER.—A correspondence consisting chiefly in word-fence is undesirable to continue. Several Correspondents in our next.

The Photographic News, April 20, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO THE CAMERA AS CLERK AND DRAUGHTSMAN—THE ADVANCE OF SCIENCE BY MEANS OF REWARDS—AERIAL PHOTOGRAPHY.

The Camera as a Clerk and Draughtsman.—Seeing that photography has made its way into so many different channels, it is, perhaps, not surprising to find the art entering our big Government offices. It may be some time before the camera replaces the city clerk, and reduces the prestige and salary of the latter within still more narrow limits; but already there are signs of photography taking the place of clerical assistants and draughtsmen in large establishments, and from the circumstance that it does the work more trustworthily and rapidly, there is every likelihood of its retaining its foothold in those quarters. In many engineer establishments and factories, where plans and sketches have to be copied, the work is done by the aid of photography, the original being simply placed above some prepared paper, and the two sheets kept in contact with one another with a couple of glass plates held together with American clips. Silver paper, such as that prepared by Carrier, is sometimes resorted to for this work, but generally the prussiate paper manufactured in Paris, and also, we believe, by the well-known firm of Marion and Co., of Soho Square, which yields a white-lined sketch on a blue ground, is employed. This paper may be purchased in very large sheets, and will keep good for months before it is used. Its manipulation is exceedingly simple, and requires no practised hand; a few washings is, indeed, all that is needed. Scientific gentlemen employ the same means for copying their calculations, after they have been at the trouble of working these out, and in this way obviate the chance of any error creeping in during the process of copying. The late Sir John Herschell invariably made use of this plan of preparing copies of important notes and data, and in this way always had his own handwriting and figures to refer to. In the preparation of copies of important documents which pass through the War Office, the camera is not unfrequently had recourse to, we hear, especially when the same are expressed in a foreign language, or contain a mass of figures the correctness of which might suffer from clerical reproduction. Besides the trustworthiness of the camera as a copying medium, its rapidity is also a quality that cannot be made too much of. By unstitching a pamphlet, and spreading its pages out upon a flat board, the former may be wholly copied in a few minutes, a task which, in the case of a strange tongue, would involve days, if not weeks. Again, tabular statements, or calculations made to assist in working out problems, whether of a scientific or general nature, may in the same way be quickly reproduced without fear of error or misunderstanding. The camera never makes a mistake in a figure, or fails to dot an i, and for this reason can always be trusted to perform clerical work with the strictest integrity and trustworthiness.

The Advance of Science by Means of Rewards.—Some weeks ago we took occasion to express our disbelief in any good being likely to accrue from endowment of research, and gave it as our opinion that nothing extra would be found out now that Government had resolved to spend the sum of £4,000 upon scientific investigators. Our main argument, it may be remembered, was to the effect that the money was hardly likely to come into the hands of those who had a claim to it, or really wanted the cash; and in any case, a man would not withhold an invention or discovery from the world for the sake of a few pounds more or less in his pocket. The popular idea is, that if you want to find anything out, you have only to proclaim a prize, and the problem is solved forthwith; How fallacious such a view is may be seen from the recent

action of the French Photographic Society. This body some months ago, determined to offer a reward for a good dry plate process, which should have all the advantages of the wet method, with any others that the discoverer might communicate. The affair has come to an end, and what is the result? Why, that there was no competition at all. There was practically only one process submitted, for other two which were sent in did not even meet the general admission regulations which had been drawn up. M. Alfred Chardon therefore walked over. We do not know what the process is that has gained for M. Chardon the honour, but since the gentleman himself admits that it is not new—by which we suppose he means that he did not work it out—we fail to see how he became entitled to the award. It is an emulsion process with alkaline development, it is said, so that it would have been absurd, indeed, to have claimed novelty. There may be, and probably is, some peculiarity in the manipulations peculiar to M. Chardon himself, but we never knew a dry plate worker yet who did not have a fad of his own. Granted that M. Chardon's process is an excellent one, as it is very likely to be, we shall be surprised, indeed, if it is superior to the many excellent processes that have appeared already in these columns and elsewhere, and which have been freely given to the world without any heralding or trumpeting forth whatever. If M. Chardon's process is a good one, it would have become known quite as readily without any prize being offered, we contend, and the making of this award, therefore, has had little to do with progress.

Aerial Photography.—The subject of making photographic observations from balloons is one which has received but very scant attention in these days of scientific progress. A military balloon committee is, we believe, still sitting at the War Office, but the gentlemen composing it have not, we hear, yet discovered a satisfactory medium for floating the machines, and, consequently, have not yet discussed the subject of taking observations. In Paris, two years ago, M. Nadar, the eminent photographer aeronaut, made many experiments in aerial photography, and, according to our French Correspondent, succeeded satisfactorily in accomplishing the difficult problem of securing camera images from a balloon. The late Sir Charles Wheatstone, who had seen M. Nadar's productions, informed us that they were the most successful aerial photographs he had seen, but that much was still required to render the *modus operandi* perfect. The gyrations of the machine, and its unsteadiness, even when tethered to the ground, were so great that only instantaneous work could succeed. Some pictures which we have seen of Boston taken from a balloon are very good, but they do not take in a very large field. They were obtained by the aid of a stationary balloon, and they certainly give results invaluable from a military or geographical point of view. The First Napoleon was so impressed with the advantages of balloons as a means of observation and of *reconnaissance*, that he organised a balloon corps, which accompanied the army in the field. With a camera to aid him, the observer could make his observations, and map out the ground before him, far more quickly than if he had but a field glass to help him. But it would be necessary to have his instruments ready, and also to settle upon and arrange a perfect system for instantaneous work; for otherwise, as one can well understand, the novelty of the photographer's position, and the circumstances under which he has to work, would interfere materially with his operations. To carry out his task rapidly and skilfully must ever be the object of an aerial photographer; but how to accomplish this is a problem evidently yet to be solved. Mr. Glaisher, the President of the Photographic Society, is one, however, who could materially help with suggestions, for the seventy or eighty ascents he has made constitute him the recognised scientific aeronaut. His experience on this particular subject is probably not shared by any other scientific man.

ON PLATINOTYPE.

BY THOMAS RODGER.*

THERE is a great charm about these pictures so produced on plain paper, the tones resembling those of a warm engraving. Added to their beauty and the rapidity of production, they resist all the usual destructive tests. By a very simple experiment I think I can illustrate to you the whole chemical action involved in this process now detailed. We have here the yellow powder ferrous oxalate, the same which by the action of light is formed from the ferric oxalate, and which forms the visible picture. Now if I, by the aid of a little heat, dissolve this in potassic oxalate, and bring it in contact with a solution of platinum, you will observe instantly a deposition of this metal in a dense black finely-divided form. This is precisely what occurs on the exposed sheet when it is passed over the potassic oxalate bath, only that the deeper shadows and gradations of the negative under the action of the light affect more or less the amount of reduction.

I am not aware that this process has been demonstrated in any of the photographic societies in Britain. Hitherto I believe that Professor Stebbing brought it before the French Society in Paris, and demonstrated it successfully some time ago. I purpose now, therefore, to occupy a few minutes in doing the same before you. For this process any kind of surface may be employed, provided it be somewhat porous, and it is better that it should have received a coating of organic matter in the form of gelatine (or, preferable, arrowroot). In the commercial prosecution of this process, ordinary photographic or other good quality of paper is treated with arrowroot. This is now placed for a moment on a weak solution of nitrate of silver (six grains to one ounce) and dried. In this form the paper may be kept for an indefinite time. When it is requisite to produce copies it is only necessary to take a solution of the chloro-platinite of potassium, and a solution of ferric-oxalate mixed, and coat the sheet therewith. Dry, and expose under the negative. The picture on development may, as we have said before, be considered beyond the reach of change, but the colour of it is rather too black to please, and, therefore, it is desirable to modify it, and this is readily done by subjecting it to a solution of gold for a short time. After the desired colour is obtained it should be put into a weak solution of hyposulphite of soda or solution of chloride of sodium for a few minutes, and from that to water; and finally, in order to remove all traces of the ferric oxalate, the print should be placed in a weak solution of oxalic acid for as short a time as may be considered necessary, and then, with a slight amount of washing, the picture may be hung up to dry. If it be desired to give a finished-looking or glossy surface to the print, this can be done by various methods; as is generally the case, the depth of shade and gradation is made more attractive.

I shall now proceed to illustrate the operation. I have brought with me a few sheets exposed to-day before I left St. Andrews; these I shall develop. After I have prepared a sheet, I shall hand for your inspection the sheets exposed this morning, and you will observe that there are two of them equally visible with the others; but you will observe them marked as having been prepared without platinum—only with the ferric salt on the exposure to the potassic oxalate bath they will entirely disappear, owing to the solution of the ferrous oxalate, no reduction being possible.

I presume that you are aware that Mr. Willis has secured a patent for this process in this country, and that he has entered into arrangements, and is associated with, in this matter, the Albion Albumenizing Company, of Glasgow and London, which Company have the right of dispensing licences. I learn that very recently the process has been also patented in France, and that a firm there have absorbed the right in that country.

The specimens of prints which I now submit to you are from several sources, and a number of them have been by myself subjected to extreme tests, in order to prove the indestructibility of the image. There is one marked as having been for twelve hours under the influence of sulphuretted hydrogen, and the half of the same picture was immersed for an additional twelve hours in the acid solution employed to form the gas. Others have been for six weeks on a floor constantly wet, and subjected to treatment only short of being trodden upon, and you will observe that there is no change whatever.

Mr. Willis has nearly completed his researches in the matter of producing an emulsion with a view of still more simplifying the process, and when he returns from his journey to the West we may expect to hear from himself on this subject. Trusting that I may not have wearied you in the foregoing remarks, and that a spirit of enquiry may be aroused on the subject, I now conclude with many thanks to you for your kind patience and attention.

LANDSCAPE PHOTOGRAPHY.

BY JOHN PARKER.*

WE have not yet reached that stage in photographic progress where clouds and landscape can be satisfactorily rendered in the same negative—at least, this can only be done under very exceptional circumstances; and the fact is that we must either sacrifice the sky to the foreground, or the foreground to the sky. Sky-shades and similar adaptations are very useful in their way, especially in preventing the obliteration of a delicate distance; but it remains true that only in the hands of the most skilful operators do you get a negative satisfactory both as to the landscape and the sky.

Perhaps the interesting suggestion to use a Nicol's prism attached to the lens may point the way to some practicable and practical solution of the present difficulty; but, until then, we must be content to produce the cloud effects in prints by a second printing from a cloud negative.

Of course it is best to take such cloud negatives from nature, and with a few such negatives, giving different characters of sky, and different directions of lighting, great variety may be produced. But with myself, my opportunities of a day in the country with the camera—that is, a *suitable* day—are so rare that I am always inclined to turn my attention to the landscape, and trust to some other means of producing the sky effects. As possibly this may also be the case with some other amateurs I take this opportunity for describing the method I now generally adopt.

I have from time to time tried various methods, but the chief of these have been either to paint in cloud effects on the negative itself, doing so on the *back*, so that the lines may be softened by diffusion in printing through the glass, and in this way only one printing for foreground and sky is necessary; or, to paint on thin tracing-paper, with china ink, a series of cloud negatives, one or other of which may be used, according to the subject of the landscape, for a second printing. The first method is only available in negatives where the sky is very thin, and the results, at least in my hands, are not very satisfactory; I therefore almost always employ the second method, which I find gives very good results if carefully used. They present this, among other advantages—that by merely turning the one side of the paper, or the other, you may change the direction in which the clouds are lighted, so as to suit the light in the landscape. And I would here suggest that the same advantage might be obtained with cloud negatives taken in the camera by removing them from the glass, and transferring them to a transparent gelatine or tracing-paper support. I do not use a printing-frame with these paper negatives. Taking the print from the frame with the landscape only printed, I pin it on

a board, and cover the foreground with a stout paste-board, or any such thing, having first laid down the cloud negative in the most suitable way for the particular subject; this, of course, all in yellow light. Then with cotton wool I shade off the sky line of the landscape, the wool being under the edge of the paste-board, so that the latter keeps it in position, while the wool prevents the sharp line which the paste-board would make in the print.

If the sky be broken up by trees or otherwise, so as to be seen in patches only, I cut holes in the protecting paste-board somewhat larger than the patches of sky to be produced, and fringe these holes round with the wool (the cloud negative, of course, being always under the wool and pasteboard, and next to the print); then laying a weight on the pasteboard to keep all in position, I expose it. In practice, I have a number of pasteboards with different-sized holes always ready at hand, and it is easy to alter the size of these to suit any particular case on a moment's notice, by selecting one larger than is wanted, and filling up the excess of space with a fragment of brown paper or an extra supply of cotton wool.

It only remains now that I very briefly give the formulae I employ, in which, however, there is absolutely nothing new. First, then: for wet plates in the field I use old collodion sensitized at least six months—longer if possible—and a distinctly acid bath. For developer I use Mr. B. J. Edward's formula, namely—

Sulphate of iron	1 pound
"	"	and ammonia	1 "
"	"	copper	1 ounce
Water	87½ ounces

This gives 160 grains to the ounce of water.

I carry one ounce of this in a dropping-bottle, and another bottle with acid water, in the proportion of one of glacial acetic acid to thirteen of water, with spirit of wine as may be required. Both of these I keep ready in stock in my laboratory, and fill the tent bottles just as required. For a seven by nine inches plate I pour into a wide-mouthed bottle, which I use as a developing cup, three-quarters of an ounce of the acid water; and as every drachm of the iron solution contains twenty grains, I can at once suit the strength to the subject, the light, and the exposure. I always give a long exposure to take up all that is in the shadows; and, if there be a great range of distances, I add just about twelve to fifteen drops of the iron to the three-quarters of an ounce of acid. This gives a strength of a little over five grains per ounce, under the action of which the delicate distances come out; and then I strengthen with other fifteen up to thirty drops, as may be required to bring up the foreground. I generally finish on the spot, and to save copious washings in the tent I strengthen, if need be, with iron, citric acid, and silver, as it is then unnecessary to wash from the first developer. When density is obtained I pour on a few ounces of water, previously placed in a six-ounce bottle in the tent; then, opening the door of the tent box, I take out the tray with the negative, wash thoroughly and in freedom in the open air, and clear with the cyanide, which I always keep in a bottle in my pocket, marked legibly "poison."

The formula for the hot-water process is exactly as in the *British Journal*, including the final wash of gallic acid, unless the plates are to be exposed within a few days after the preparation. With the gallic acid they will keep for months; but I always try to have them developed as soon as possible after exposure—say within a week or so, or sooner if no gallic acid be used. After rinsing with water, before applying the gallic acid, I flood with a little distilled water. I should have mentioned, also, that after removal from the silver bath I soak in two trays of distilled water, and then rinse well under the tap, finishing with distilled water before pouring on the albumen. The first washing, at any rate with distilled water, I think very important, as, unless the water be pure with which the free nitrate of silver is removed, insoluble salts of silver may be formed

on the surface of the plate, which may seriously modify the after-results. The extent of this evil will, of course, depend on the nature of the water used for washing; but, unless the composition of the water be known, it is safest to take the precaution of beginning and ending with distilled water.

The formulae for the collodio-albumen or Taupenot plates are numerous, and I have used sometimes one, sometimes another, without noticing much difference. That of Mr. Price is very good, only I prefer to pour on the albumen instead of using it in a bath, as I think the bath method is more liable to cause air bells in the albumen, of which it is very difficult to get rid. His formula for the albumen is as follows:—

Albumen	8 ounces
Water	1 ounce
Glacial acetic acid	24 drops.

Stir well up for two or three minutes with a glass rod, and after rest for an hour, strain through muslin; then add half-a-drachm of the strongest liquor ammonia, and iodise with forty-two grains of iodide of ammonium and six grains of bromide of ammonium. With a small bit of camphor in it, or a few drops of carbolic or salicylic acid, it will keep good for years—certainly for a whole season.

The collodion, both for this and the hot-water process, should be open and powdery, so as to give a surface, when sensitised, that will receive and retain as much of the albumen as possible. *Steps of Process:*—1. Dilute albumen subtratum. 2. Collodionise. 3. Sensitise. 4. Wash well. 5. Bath of common salt. 6. Wash well again. 7. Flood with albumen, and pour off first dose in the sink; flood with second dose, and let it flow back and forward so as to sink well into the film. 8. Drain till surface-dry, then dry in hot water bath at boiling point. All this may be done in daylight, and the plates in this stage will keep for years, so that a large stock may be prepared. When wanted for use, lay, face down, on a fifty-grain aceto-nitrate bath for about half to three-quarters of a minute—not longer; wash thoroughly—first in a bath of distilled water, then under a tap, finishing with distilled water. Finally flow over a two- or three-grain solution of gallic acid, and dry without heat. No backing is required, and they will keep a long time in good condition.

Alkaline development is suitable, though they may also be developed with plain pyro., and finished with acid silver.

OXYGEN-PRODUCING APPARATUS.

BY M. NOTON.*

I HAVE another change in oxygen machinery to show you to-night; but before I open my budget I must first congratulate Mr. Chadwick on his production in that line at the last meeting of this Society.

It appears to be clear now that there are only two ways of using a mixture of chloride of potash and manganese—either it must be in the loose state, dry, or damped and moulded into solids of any convenient shape. The first condition will belong to all fixed plant and filling gas bags for customers. The second relates to portable apparatus. The fastening of the plug to the bottom of the inside of the retort has always been a great hindrance. Mr. Chadwick has grappled with this difficulty in his cakes by having a subtratum of manganese only in contact with his hot cast-iron plate.

During the last two years or so I have tried several ways to stop the adhesion. First, I coated the inside of the retort with a thick wash of whiting and water, also with clay wash. These did pretty well for one or two plugs, but the coating came off soon, and had to be renewed. As this was unsatisfactory, I tackled the plugs themselves; some were chalked all over, and others had whiting, red ochre, and clay wash. The wet plugs from the mould

* Read before the Manchester Photographic Society.

were covered with fine black oxide of manganese, but they were too tender to bear rolling in it; all this involved more labour and time. Then there was the swelling of the plug when the gas came off. The obvious remedy for this is to have the retort larger inside. When a plug is too large it not only is cemented to that part of the metal it rests upon, but fills up the inside so much that there is no getting it out comfortably. This defect I tried to remedy by making a hole through the other end of the retort. I could then drive the plug out. This involved an additional quantity of tackle for closing that hole. I afterwards made a retort tube of equal bore throughout. This was used at Mr. Brothers' lecture on the transit of Venus, and it is now part of the new machine, with the exception that it would be better if of a larger bore. I cannot see that there is any room for further improvement, the connecting or disconnecting being so prompt.

This new arrangement may be considered to be of the parallel vice type: in fact, it is one, the jaws being "stepped" by two brass cups for holding the retort tube over the nine jets of aerated gas. The retort tube has a temporary handle fitted to it, and this tube so provided is the only loose article about the machine. The tube will generally be hot, but need not be touched, so that that objection is put out. Apparently the next serious difficulty is getting the cooked plug out of the hot retort. On the supposition that the bore of the tube is large enough to allow for the expansion of the plug, there remains only the adhesion to overcome; when that is broken all the rest is easy. To do this I intend to make a screw pusher; there will be an abutment similar to one of the vice jaws, provided with a brass cup having a hole through as large as the bore of the retort tube; at the other end there will be a screw. One end of the hot retort tube will be put to the abutment, a few turns of the screw at the other end will soon make the plug move on, and that difficulty will have been got over without any especial preparation of either the retort or the plug. I am certain this will be the result. By slackening the grip of the vice a little the retort may be rotated nearly two-thirds of a revolution. When I first began to make plugs I dried them on the top shelf of the oven. I could smell them, and having an idea that I was drying some of the oxygen off, I gave up that practice, and let them dry slowly.

The easy rotation of the retort tube pointed to a theory I had. My impression was, that although a plug appeared to be dry, it yet contained water of crystallization in the chlorate; that this water came out as vapour, condensed on the colder parts, ran down to that part of the plug resting on the bottom, wetting it, and so causing the fastening. Now, I thought by turning the retort tube backwards and forwards it would be a preventative, as the plug could roll more than half a revolution. Upon trial the plug stuck as fast as ever. The next experiment made was to find whether this water came over as surcharged steam with the oxygen. The washing bottle was weighed, some short pieces of plug were cooked, and when the bubbling had ceased the washing bottle had increased in weight six grains. This was but a rough experiment, and intended merely as a preliminary.

(To be continued.)

AN ENERGETIC DEVELOPER.

BY ERNEST BOIVIN.*

FOR some time past photographers have paid attention to powerful developers. I read with interest, in one of the recent numbers of the *Moniteur de la Photographie*, the details of an accelerated developer in which sulphate of iron, sulphate of magnesia, and formic acid were the main constituents, the same being said to diminish considerably the time of exposure. This developer I experimented with thoroughly, and I must say I did not get any better results than those obtained by M. Baudoux. I found the same

defects that he has alluded to. Nevertheless, I utilized the indications furnished by the anonymous author, none of which helped me to secure more successful results.

It would be, however, a very important point if we could secure with facility greater rapidity by employing a developer more energetic in its action. If such a one could be discovered that would admit of a shorter exposure being given, it would, without hesitation, be employed in preference to all others.

In the meantime, before I make known the results of some new experiments of mine on the subject, I may say a word on behalf of an energetic developer which really does permit the exposure to be diminished, and which I have used for some time past with very good effect. Not only does it permit me to diminish the exposure by pretty well half, but it acts, too, with the greatest regularity, imparting always to the clichés particular softness and harmony. The negatives, indeed, possess a character of their own, and show very great detail. This is the formula I employ:—

Water	125 cub. cents.
Sulphate of iron	6 grammes
Sulphate of copper	2.50 "
Acetic acid	8 cub. cents.
Alcohol	5 "
Ammonia	A few drops.

After the ingredients are mixed together, the liquid is permitted to stand for a few hours, and is then filtered.

This developer will keep good from eight to ten days, but it is always preferable to use it when newly made, especially in the case of portraiture. As soon as the plate is ready to be developed, the quantity of liquid necessary for the purpose is poured into a glass or cup, and before it is thrown over the plate a few drops of a saturated solution of acetate of lead, made with distilled water soured with a little acetic acid, are added. The developer is agitated a bit after the lead solution is added. On the application of the developer the image appears gradually, the plate maintaining a very clean appearance throughout the whole course of development, and all the details appear in such a marked manner that it is in general unnecessary to have recourse to intensification.

The energy of this developer depends especially upon the addition of the acetate of lead to the copper-iron solution. It is known that the acetates and nitrates of lead have the power of augmenting considerably the energy of reducing agents, and to furnish, moreover, a deposit, the colour of which is particularly suitable for the film of a photographic cliché.

With the aid of this developer, the preparation of which is so easy, I obtain in ten seconds, in a room lighted up only by an ordinary window, portrait pictures which, if not exactly wonders, are, nevertheless, satisfactory as photographs and striking as portraits.

THE DEVELOPMENT OF EMULSION PLATES.

BY DR. LIESEGANG.*

THERE are, it is well known, two kinds of collodion-emulsion—that prepared by the mixing together of normal collodion, iodine or bromine salts, and nitrate of silver; and, secondly, that which is poured into water after preparation in this way, the insoluble portion being collected and dried, and afterwards dissolved again in alcohol and ether.

The first (unwashed emulsion) is poured upon the glass plate, and as soon as the film has set is put under a water-tap, or placed in a bath of water to be washed, when a preservative is applied and the plate dried. The operation of drying, by reason of the sticky, watery character of the preservative mixture, requires to be undertaken with considerable care, and it is only the silver bath that is dispensed with in the preparation of such plates. Whether there is any saving in the manipulation is, how-

* *Moniteur de la Photographie*.

* *Photographisches Archiv*.

ever, another question, because of the elaborate preparation of the collodion; and so long as emulsion plates of this kind do not afford us better results than wet plates prepared in the ordinary way, it will be a question whether there is anything gained by dispensing with the silver bath.

It is, however, another matter to work with washed emulsion, for in this case the manipulations are reduced to the simple pouring on of the collodion. This is a great gain to busy people, to those who do not care for much exertion, or to travellers who require to carry about with them no awkward dishes and inconvenient silver baths.

It is great advantage to work with washed collodion. The preparation of three plates, measuring nine inches by seven, may be accomplished in about five minutes' time. There are no preliminaries to be undertaken, no silver bath to filter, no dishes to clean or to fill with water, no residues or draining from the plates to collect, no preservative solution to make, filter, or apply, and, finally, there are no particular arrangements to be made for the transport of a large amount of baggage, a matter of considerable importance in the case of long journeys.

The unwashed emulsions give rise to a film from which the soluble decomposable ingredients crystallize out (the nitrate salts), and hence arises the necessity for removing such salts by washing. The application of water, however, removes the soluble nitrate of silver at the same time, as well as other substances necessary to the formation of a photographic image, and the consequence is that, after washing, the application of a preservative is necessary, consisting of a solution of gum, albumen, tannin, pyrogallie acid, salicine, &c. In the washed emulsion these injurious soluble substances have been removed by previous treatment with water, and for this reason no subsequent washing of the film is necessary, the so-called sensitizing substances being imported by bathing the precipitated mixture of collodion and bromide of silver in solutions for the purpose.

No stress ought to be laid, in photographic processes, upon the greater or less labour involved if the result shows a difference in the quality of the pictures. The end is the object to look at, and we should not consider whether a bath is to be used or not if superior results are secured in one way or the other. But if the results obtained are equally good in the case of two different processes, then undoubtedly the simpler of the two deserves to be chosen.

The washed emulsions, as they are now to be purchased in commerce, have been found to keep well in the hands of many landscape photographers, while this journal has given, by way of frontispiece, a proof of the qualities of pictures produced by the substance. So far as the cost of such emulsion is concerned, it may be remarked that for coating a dozen plates of twenty-one by sixteen centimetres, sixty cubic centimetres of emulsion are necessary; as the emulsion costs about forty marks (or shillings) a litre, the coating of a single plate of the size mentioned would cost about twopence.

In the preparation of three plates, five minutes, as already mentioned, is all the time required. To clean twelve plates of twenty-one by fifteen cents., and then to albumenize them, five-and-twenty minutes are necessary, and twenty-five grammes of diluted white of egg. The entire period necessary to clean, albumenize, and collodionize each plate is, therefore, about four minutes.

The development of dry plates is, generally speaking, very different from the treatment of wet ones, because the latter are developed in the presence of much nitrate of silver, contained, in a great measure, in the sponge-like film of the wet plate. Dry plates, on the other hand, have but little free nitrate of silver solution about them, the image being frequently produced by the action of the alkaline developer upon the difficultly reducible bromide and iodide of silver. The principal difference is that, in the development of wet plates, a vigorous picture is very soon produced, the colour of which, whether the plate has been exposed a long time or a short one, is always the

same, and does not change in any marked degree by the treatment to which it is subjected. In the case of the dry plate, however, we have a very thin image to begin with on development, which gradually acquires strength, and it is particularly in regard to this matter that we desire to say a few words.

Those who are not blessed with good eyes will be scarcely able to judge properly of the result produced by the application of pyrogallie acid solution (without acid or alkali), for the phantom picture is very difficult to watch in the orange light of a lamp or window. The difficulty in judging of the tone of the image in respect to its printing properties is also very great, and here we make a remark that there is generally a tendency to overdo the matter. Exposure, alkaline development, and acid intensifying must be kept in harmony with one another. The negative need not be so very dense, nor appear to the eye opaque, for it does not lose much of its density on fixation. Beginners are very apt to intensify too much. Of all the modes of development with sulphate of iron and silver, pyrogallie acid and silver, and pyrogallie acid and alkali, the last appears to be, in conjunction with silver intensification, the best suited for washed emulsions. After some hundreds of experiments undertaken in the course of last month, I have come back to this method, although it cannot be denied that by the defective application of the same the negative is much more easily injured than is the case when acid pyrogallie acid and silver are made use of. In the case of equal exposures, however, the negative developed by alkaline solution has much more detail than that treated with an acid liquid, and to secure similar results with two plates by alkaline and acid development, it is necessary to give the plate to be treated with acid solution two or three times as much exposure as the other. The main difficulty in the case of alkaline development is, as above stated, the difficulty of estimating the value of the phantom image first brought out upon the plate. If the alkali, whether it is ammonia, carbonate of ammonia, or carbonate of soda, is permitted to act too long or too vigorously without the addition of a sufficient quantity of bromine salt, there is produced, if the plate has been overexposed, a thin image which is found very difficult indeed to intensify. In the case of properly exposed plates, however, the images are developed clean, clear, and vigorous. To take a sunlit landscape with an apertic double lens of four centimetres' diameter, and a two centimetre aperture, an exposure of from six to ten seconds only is necessary.

To develop, I proceed as follows:—I take up the plate with the pneumatic holder, and cover it at one sweep with spirits of wine (any hesitation in this operation will give rise to streaks). This spirit is washed off after thirty seconds with ordinary water until the film does not appear to be greasy any longer. I then pour on my pyrogallie acid mixture, which consists of one gramme of the acid dissolved in eighty grammes of water. The outline of the sky appears in about twenty seconds, and soon after the half-lights of the image begin to come out. The pyrogallie acid is then poured off into a clean glass or developing cup, and mixed with three or four drops of bromide of potassium solution (1 in 24 strength) and ammonia (one part in eight parts of water), and with this mixture the cliché is still further developed until all details are apparent. The image is then washed, and an aqueous solution of citric acid (1 in 50 strength) is poured over it. This removes a fine veil that covered the picture.

The intensifying of the image is carried out with the same pyrogallie acid solution, mixed with a few drops of silver liquid made up of—

Nitrate of silver	1 part
Citric acid	1 "
Water...	15 parts.

The negative under this treatment remains beautifully clear in the shadows, and assumes an intense olive-brown tint.

Meteorological Report for March. By W. H. Watson	192

PARIS INTERNATIONAL EXHIBITION OF 1878.

As many of our readers are aware, the time originally announced as the limit within which applications for space to exhibit in the photographic department of the International Exhibition to be held in Paris, next year, has already elapsed. The necessity of an early knowledge of the space required, in order to aid in making the general allotments to departments, caused a somewhat unusually early date to be fixed as the time within which applications for space should be made and intending exhibitors in all departments were requested to apply and state the space required, not later than the seventeenth of March, now a month ago. We think, however, that we may safely assure readers who have failed to apply, and wish to exhibit, that applications now sent in will meet with favourable responses. Intending exhibitors should, however, lose no time in sending to the Secretary, P. Cunliffe Owen, Esq., C.B., at the offices of the English Commission, Canada Buildings, King Street, Westminster, for forms of application for space, which should be filled in without delay.

There is one difficulty which has possibly deterred some from making applications for space, who, but for this difficulty, might willingly exhibit. The general conditions of exhibition as stated in the papers issued by the English Commission contain an intimation that no wall space would be provided, there being no interior walls in the building. All exhibitors requiring wall space for their contributions must provide for themselves by the erection of screens, &c. Such a plan manifestly presents serious difficulties in relation to photography, as nothing could be more inconvenient than individual action in erecting a number of screens, each photographer one for himself. A suggestion is made in the conditions as to doing this conjointly with others. To do this efficiently involves a scheme of confederacy which there is no machinery to establish or work. Possibly the Photographic Society might, if duly moved to action, have established a committee to undertake the management of such an arrangement. Nothing of the kind has, however, been done, and many photographers we know contemplate with dismay the idea of erecting screens for themselves on unknown conditions, at an uncertain cost.

Ten years ago, when the last International Exhibition was contemplated in Paris, a similar difficulty existed at the outset. It was solved, however, in a manner very satisfactory to English photographers. The English Commission undertook the erection of screens, upon which the works of English photographers were exhibited, without cost to the contributors. Whether similar arrangements can be made for the forthcoming exhibition or not we are unable to say, but we have reason to believe that some

arrangements will be made to save photographers from the necessity of the individual action to which we have referred. But it is necessary, first of all, that a definite idea of the space required should be placed before the Commission. Hence it is important that any intending exhibitors should apply without delay. We shall take care to bring before our readers any further arrangements which may be made in relation to the display of their contributions.

SOLAR ENGINES.

THE sun has been made to do a great many things in its day, and just now there appears to be a good deal of talk in Paris, in scientific circles, of engines which are to be driven by the sun's rays. We do not suppose the engines in question have anything to do with Mr. Crooke's light-mill, as the radiometer was first termed when it was believed that light, and not heat, was the agency by means of which it acted, but are seemingly based upon the evaporation and condensation of liquids and gases. It is well known to chemists that some gases—like that of ammonia, for instance—may be compressed without difficulty in such a way that they represent a store of energy, and several suggestions are already before the world for securing motive power in this way. Mr. Maxwell Lyte, whose name as an early photographer is well known, is the author of an invention of this kind, the application which he desires to put it to being, we believe, mobile torpedoes. Already compressed air is employed for a similar purpose; but the air-pumps and complicated machinery necessary to charge machines with air at the terrible pressure necessary will be much simplified if ammonia can be employed instead.

In Paris, at the present moment, there are two solar machines which promise so well to become useful that already the Minister of Commerce has interested himself in them, and spoken loudly in their praise. These are the solar engine of M. Mouchat, and another machine, devised by M. Foucault, which is described as an ammonia machine to be driven by the sun's rays.

It would be premature to say a word for or against such projects before details of their construction are before us; but unless the sun pays us more frequent visits than it has done lately, or the machines are not dependent upon its shining, they will not be at work for long together. But it is, no doubt, solar heat, and not sunlight, that is required for working the newly-devised engines.

PHOTOGRAPHY AND LICHTDRUCK IN RUSSIA.

THE *Photographischer Archiv* publishes a letter from a Russian correspondent, M. Gustav Ra, who, writing from Jelefs, gives an account of mechanical printing in the land of the Czar. He says:—

In the following lines I have taken the liberty of giving you the particulars of a modification of the photo-lithographic process, which will doubtless be of interest to those who occupy themselves with such work. It is well known that transfers upon paper suffer from the disadvantage that the paper on being wetted expands and contracts irregularly, and the prints that are pulled off do not then correspond any longer, so far as dimensions are concerned, with the original image, a defect which is very important, whenever, for instance, topographical work is undertaken, the copying of maps, &c. For this reason tin-foil and other materials have been suggested to bear the transfer. The process I am about to describe is quite free from any unequal enlargement or contraction of this kind.

Good photographic paper, unprepared in any way, is washed in a weak alkaline solution to remove all trace of sizing, and is then dried by being placed between sheets of blotting paper. Or, if it is to be secured, so-called Chinese paper may be made use of for the same purpose. A sheet

of patent glass, well cleaned, is rubbed over gently with powdered talc, and then coated with normal collodion. As soon as paper and glass plate have dried, the paper is cut into pieces which are somewhat larger than the collodionized plate; these sheets are floated upon a solution of gelatine made up of—

Gelatine	1 part
Water	10 parts
Spirits of wine	1 part

Care is necessary to avoid air-bubbles during this operation, as also in the further one of placing the sheet upon the glass plate in such a way that the margins of the paper overlap the plate in every way. The paper borders are bent round, and made to attach firmly to the glass plate. The paper is next treated two or three times with the same solution of gelatine, and when dry the surface is ground smoothly by means of shave-grass. The smooth and even surface, well dusted, is once more covered with a carefully filtered solution of gelatine, and then dried again. Such prepared plates will keep a long time, and it is advisable that a stock of them should be kept.

To secure a print, one of the plates is dipped into a solution of—

Bichromate of ammonia	1 part
Water	12 parts

and permitted to remain therein until the paper appears yellow from the glass side. The adherent liquid is removed by means of filtered paper, and the plate is then dried at a temperature which should not exceed 20° Reaumur. If, instead of bichromate of ammonia, potash is employed, then you may safely employ temperature double as high as the one mentioned without the quality of the plate suffering.

The printing should be got over as rapidly as possible. The best results are given by a negative which is clear in the shadows and opaque in the whites; and the printing is at an end when the image is to be seen faintly visible from the glass side. As soon as the plate comes out of the printing frame it is washed in cold water, to remove all the undecomposed chromium salt, and, finally, by means of warm water, the still soluble gelatine is washed away from the exposed film. The last washing with warm or hot water must not be hurried; at the same time it requires to be thoroughly carried out in order to free the pores of the paper from every particle of soluble matter.

After the print has become perfectly dry, it is put into a bath consisting of one part of neutral tartrate of potash and eight parts of water, and allowed to remain therein so long as is necessary for the light parts to be thoroughly soaked. Taken out of this bath, it is put into another made up of one part of tartaric acid and ten parts of water. In this second bath the impression remains only for several minutes, and it is then taken out, drained, and dried between leaves of blotting paper. It is now ready for inking; but before you proceed to this last operation the plate is held for a few minutes over a vessel of boiling water, in order to impart to the print a slight degree of moisture, and then it is inked by passing over it a roller treated with a firm transfer ink.

If the operations have all been conducted with proper care, the image will, on the application of the roller, appear of exquisite clearness, and far before other transfers that are made in the ordinary way. Finally, the dry transfer is separated from the glass plate by cutting through the margins of the paper, and the same placed upon zinc or stone in the ordinary manner. The preparation of the transfer with tartaric acid is especially useful in the case of large surfaces of white, which contain but few lines, for the acid appears to preserve such portions, and to prevent them from being smeared with ink.

In conclusion, I may say a few words on the subject of Lichtdruck in Russia. That a process—which has so great a future before it—has already taken root in the country, may be proved by the magnificent works of M.M. Schindler et Mey, and the firm of Scheerer and Nabholz, of Moscow. A

few months ago I had an opportunity of visiting the arrangements made by M. Schindler for working this photo-mechanical process, and was truly astonished at the extent of the workshops occupied in this branch alone. Among many works that were in course of printing by Lichtdruck, and of which large editions are produced, two deserve especial mention, namely, an album on "National Russian Architecture," and another on "Russian Fabrics," the illustrations of which were all from negatives taken from nature, and would be of interest to others besides the inhabitants of this vast country.

TRANSATLANTIC WRINKLES.

BY LAFAYETTE HARRISON.

No. III.

I MUST premise right here, that the above heading is almost a misnomer, except in so far as the reader may glean fresh ideas by a method of deduction; yet that this paper may not go forth a foundling, but may be able to claim some relationship to its predecessors of the same name, why—let it stand.

The subject is, "The Difference between English and American Photography, examined through American Spectacles." But let no one imagine that I am about to undervalue Britannia's sun-painters, or to panegyrise Columbia's—"perish the thought!" I shall deal not so much with the skill of either, as with their appliances for working; and, further, endeavour to point out the manner in which certain advantages now enjoyed by those in the States may be introduced and adopted in the "mother country."

Light.—Ah! there English photographers are at a disadvantage. That beautiful sky, of deepest blue, roofing in the whole territory for two-thirds of a year, cannot be shipped from America, like the meat. No, we must be content with what we have, unless M. Scotellari can help us with his late photological discovery, which I doubt. One point alone can I see wherein any improvement may be proposed. It is this. Banish as much of that white (?) muslin, calico, linen, or whatever it may be with which you moderate (errata—*shut out*) your light, and substitute *white tissue-paper*. Your individual ingenuity will devise the readiest means, frames or what not, but of this be assured, if you are a master of lighting—without which, although a photographer, you cannot call yourself an artist—you will, if you have not already tried it, find that you have a new brush placed in your hand, with which finer pictures may be painted than you have ever yet produced.

Cameras.—English camera-boxes are made more strongly, more carefully, and are finished with more neatness than American; but at the same time a greater degree of accuracy can be obtained with the latter. The system, moreover, of focussing with the back of the camera, which runs in metal or hard-wood guides, is of great assistance. Dr. Vogel has so thoroughly exhausted this subject, that it would be superfluous for me to do more than express a wonder that English camera-box makers have not adopted the "sliding back, the lateral swing (for portraiture), and the glass corners to the 'kits' in the plateholders." Why do not photographers demand any obvious improvement? Stock-dealers will not take the trouble; it is not to their interest, they think; the movement must come from the buyers. One English improvement I have observed with much interest, viz., the "roller slide." It is so ingenious, yet so simple, that Americans may well adopt it with advantage.

Backgrounds.—Upon this subject I do not think that I shall find a dissentient when I state that American pictorial photographic backgrounds are, as a rule, artistic, and do much towards elevating photography; while, on the other hand, those sold in this country are, as a rule, such

deals, and oftentimes draws so out of perspective, that when used they eclipse whatever may be artistic in lighting and posing, and thus the whole is marred. There are exceptions, I suppose. I have not been so fortunate as to see them.

There are grand artists in England, and the theatres prove that there are also wonderful scene-painters. Why in the name of wonder cannot one of these gentlemen step forward and realize a fortune? From my short experience of Englishmen, I feel sure of this, that when a really good article is offered them they do not for a moment begrudge paying a fair price. Backgrounds as now sold here are too cheap to be good. In connection with this, I cannot refrain from mentioning the name of Seavey, whom I consider at the present moment by far the finest photographic background painter living. I never yet have seen one piece of even indifferent painting turned out of his studio—all are "o.k." I understand that Mr. Atkinson, of Liverpool, has become his agent. If this be the case, I would advise all first-class photographers who wish to adopt the best of everything to see them for themselves. I know nothing personally of either gentleman, and my advice is, therefore, disinterested.

Accessories.—Let me dismiss this subject with the brief remark that in both countries beautiful accessories are to be had for sufficient money, and proceed to make a suggestion that is not all my own, although I believe I first introduced it in the rough. I put it to each photographer if he is not always endeavouring to procure new furniture, so that he may have something different in his pictures? Do not "that eternal chair" and "that everlasting cabinet" become monotonous? You have turned them every conceivable way—except bottom upwards—and you are heartily sick and tired of them. What are you to do? Buy something fresh. You do so. It probably runs you into (say) from three to five pounds, if it is worth anything at all. At best, it is only one thing, and before the season is half over you are hankering after some other affair. Receipts will not permit further expenditure just then, and so you grumble away, and say what wonders could be done if you only possessed so-and-so. Now could not this be overcome by a

PHOTOGRAPHIC FURNITURE CLUB?

If some photographic society, or enterprising stock-dealer, would take up the idea, I fancy it would work well.

Let there be an annual subscription, varying in price, somewhat after "Mudie's" system of Class A, B, and C, in return for which the subscriber should have the use of photographic accessories, proportionate in value to the amount of his subscription, for a stated number of weeks, at the expiration of which time he could exchange it for other articles, or, if he liked, purchase it at the ordinary figure, less so much for amount of subscription, extending over the time it had been used. An annual sale would, with the subscription money, keep the thing running. I know of photographers who would gladly hail such an institution with joy. Think it over, and if it seems feasible let that vague "someone" who is always to do such things start the club, and see if it won't soon run of its own accord. This is the idea in the rough—shape it.

Albumenized Paper.—I have personally worked many English, German, and American albumenized papers, and state, as the result of long and varied experience, that a paper which I have tried, both in England and Germany, to procure for my friends, but so far without success, used extensively in the States, bearing the brand "S. and M., Dresden," is the finest make. It is a double-gloss paper, and of the two, pink and white, I prefer the former. Next to this I should reckon "Durand's;" then the "Cross Sword." Will not some one look around for this said "S. and M." and introduce it?

I had intended to touch upon one or two minor topics, but space will not permit.

PAINTING PHOTOGRAPHS.

BY JAMES MARTIN.

A SUBJECT which has come under recent consideration is the application of wet pigments and dyes to chemically-prepared surfaces, or, in other words, the tinting and painting of photographic pictures in water colours. Miniature painting, although it may be considered under this head, yet it may be executed by affixing a properly-prepared photographic print to the back of the ivory card on which the miniature is to be painted; its semi-transparency will allow the print to be sufficiently visible to enable the artist to trace its outlines and its shadows, if he allows it to remain affixed behind the ivory card will tend somewhat to shorten his labour. It may also be roughly tinted, the colour showing through the ivory card with good effect; but for my own part, were I about to paint a miniature, I, after having used the subjacent print to obtain the outlines required, should remove it, as the tints would be purer, and there would not be the risk of its being done by any ignorant or mischievous person, and the whole effect spoiled.

It now becomes necessary to take into consideration the chemical constitution of the colours, so that they may prove harmless to the print over which they are spread; this can only be proved by experiment and experience. I think some interesting facts might be discovered if such were made in this direction, but it may be presumed that what may be termed simple colours—such as the ochres, earth, and vegetable colours—will be more likely to prove innocuous than chemically-prepared substances. But I do not see how the use of some of these is to be avoided; such, for instance, as vermilion, which is a preparation of mercury and Prussian blue, which is a prussiate of iron; also Naples yellow, which is an arsenical colour, is sometimes very serviceable. Seeing this, I am somewhat at a loss what colours to particularly recommend in preference, as I have not experimented much in this direction. Also the style of colouring is somewhat peculiar, requiring the tints used to be bright and transparent, to overcome the heavy dulness of the shadows of the print. Thus it will be seen that if a print is to be merely tinted, opaque colours are not admissible; but should it be intended to produce a finished painting, both opaque and transparent colours will be required, thus allowing the artist the more extensive selection. As my practice was in oil colours, I can only give the palette I formed for that purpose; but I know that certain colours are changeable, and will fade, such as gamboge, Prussian blue, asphaltum, lake, sap green, and Antwerp blue; this more especially the case when used as water-colours. The selection I made, and which I have found to resist the effects of time, as oil colours, is as follows: Indian yellow, Naples yellow, yellow ochre, burnt ochre, raw sienna, burnt sienna, the madder lakes, burnt ditto, Indian red, light red, Venetian red, vermilion, raw umber, burnt umber, Vandyke brown, copper brown, Prussian blue, Guimet's ultramarine, black-lead, and ivory black. There may be others as useful and permanent as these, but as I have not used them, I do not give them.

I think if photographic prints were secured by washing them over with a thin spirit varnish before colouring, it would remove greasiness, and render the effects of chemical colours inoffensive.

AN UNPATENTED CARBON PROCESS.

Dr. Vogel describes, under this title in our Philadelphia contemporary, a process by Mr. Friedlein, of Munich. A little examination suggests, however, that it is, in reality, merely a colourable imitation of the process patented by Mr. J. H. Johnson, seven years ago. Dr. Vogel says:—

"In America there is at present a lively interest prevailing in regard to the carbon process, yet this process is debarred from general use by existing patents, not taking into

account the hindrance offered by the climate in summer. I think, therefore, I will be doing the American photographer a special favour, by informing him of a process (not patented) for producing pigment pictures, a description of which was first given by Mr. Friedlein, at Munich,* who has prepared a pigment tissue which he has brought into trade. For a sensitising bath he uses—

Bichromate of potassium ... 30 parts
Water ... 800
Carbolic acid ... 1 part.

"For transferring and developing, Mr. Friedlein takes, if a single transfer only is necessary, a separately prepared rosin-paper. First, dissolve 30 parts rosin or white shellac in 100 parts strong alcohol, and filter. Second, dissolve 30 parts gelatine in 500 parts warm water, and filter. To the clear solution add five parts glycerine. Mix both solutions, first and second, when warm, and keep it in well-corked bottles; put a coating of the warm solution on Rives paper, not too thick, and hang it up for drying. This is the rosin paper, not patented as yet.

"If you wish to develop a sensitized carbon tissue on this paper, you have to dip it, and also the tissue, in water; take both out, and press them together with the equegee, afterwards press them a short time between blotting-paper.

"They are then to be developed by means of warm water. The developed pictures must be dressed (tanned), and are then ready. They are inverted in position, and without gloss. If you desire to have them glossy, operate in the following manner:—Dissolve 80 parts borax in 1,500 parts of water, and add afterwards to the boiling solution 300 parts of shellac. Boil several hours till the lac is entirely dissolved. Afterwards add to four parts of the cold solution one part alcohol, and filter. A little bit of carmine added to the solution will give it a nice colour.

"As soon as the picture is rinsed with cold water, the shellac solution is to be poured on in a similar manner to collodion; then dry the picture, after which it shows a very fine albumen gloss. For a double transfer, Friedlein recommends only glass. He does not think much of a double transfer with flexible support. He pours over the glass plates a solution of 30 parts gum-dammar in 400 parts benzole; shake the gum at first in a bottle with a little benzole, whereby it receives a milky colour; then add the other parts of benzole, and filter through paper. This mixture is poured over the plates like collodion, after which let them dry; then the sensitized tissue, under water, is to be brought in contact with the plate and pressed on; afterwards developed. The developed picture, in a wet condition, is to be pressed together with the above-mentioned rosin paper, exactly as in the English process. When dry, the picture springs off itself.

"Should the pictures remain on the glass, then a glass without any coating is to be used, on which the pigment coating sticks very well. The picture is to be pressed on it and developed.

"You see by this that it is possible to make carbon pictures in another way than the patented one, and whoever has tried his hand in this manner will soon find further means."

VIOLET LIGHT IN THE STUDIO.

PROFESSOR STEBBING has something still to say for Scotellari's plan of using violet light. He suggests that the studio should be arranged to reflect violet light. Writing in our Philadelphia contemporary, he says:—

"A short time ago I was again invited, by a celebrated Parisian photographer, to be present at a new trial of Mons. Scotellari's idea of the violet light for studios. Although my friend, Mr. Gaffield, writes in your journal, 'From all that I can learn from intelligent photographers, &c., this appreciation did not hinder me from going to the

rendezvous in company with the Messrs. Downey, photographers to the Royal Family of England.

"The following experiments were made:

	Violet Light.	White Light.
1st. ...	15 seconds	15 seconds
2nd. ..	7½ "	15 "
3rd. ...	8 "	16 "
4th. ...	6 "	9 "
5th. ...	9 "	6 "

The first and last were in favour of the violet light, the three others in that of the white.

"Now it must appear very strange to the readers of the *Philadelphia Photographer* that, by an equal exposure, the same results are obtained in Paris, whereas, in America, Mr. Gaffield, and a gentleman who signs himself R. J. O., cannot come near those results. I will endeavour to explain this. The two last-named gentlemen are quite correct in their assertion, because they employ the violet light by transmission, which cuts off a considerable proportion of the chemical rays. Mons. Scotellari also cuts off some of the chemical rays, but by having the whole room of a violet colour he gains a certain part of what he has lost by the sum of light reflected upon the model, and so he succeeds in making a negative in the same time as with the ordinary light.

"I am convinced that if he had contented himself with only proposing that the walls, reflectors, &c., of the studio, and even the side lights, should be of a violet colour, he would have obtained a legitimate success; as it is, by grasping at the shadow he has lost the substance; whether it was from ignorance, or from a desire for 'filthy lucre,' I am at a loss to know. Honour would have been obtained by him had he informed the public that violet surfaces reflected the maximum of light received, and greater rapidity could be obtained by employing violet screens, &c. But no patent could be obtained to prevent photographers from painting their walls of a violet colour, or from using violet blinds, &c., so he was obliged to propose to paint or daub a violet colour over the glass in order to obtain a patent, and have a sale for his composition. In this he has hardly succeeded, and his proposition will soon fall into oblivion if Mr. Gaffield, or some other courageous gentleman, does not take the matter in hand, and make some experiments upon the violet light, not as a transmitted medium, but as a reflected agent."

Correspondence

ARTIFICIAL LIGHT FOR PHOTOGRAPHY.

DEAR SIR,—I was much pleased by reading the critique of Mr. Wilson's upon my idea of the phosphoric candle, which is not only given with kind and gentlemanly feeling, but also contains some valuable hints in furtherance of the object. As he observes, the idea is only a crude one, and requires careful experiment before it could arrive at perfection. I know that phosphorus burnt in common air evolves the dense vapour of phosphoric acid (PO) as he states, but I believe that this is generated much more slowly when burnt in oxygen gas. But it is so long since I experimented with phosphorus that I am not certain about the phenomena produced; but I recollect that the light was a most powerful one, and, I believe, for the short periods of time the light would be required for photographic purposes, that the slow accumulation of phosphoric acid would not prevent its use. Of course there would be required some sort of lantern or other movable appliance, so that the light could be thrown in the required direction upon the object to be photographed, and also that its acrid vapours shall be entirely excluded from the studio. With these remarks I must now leave the matter in the hands of those of your readers who have the time, inclination, and ability to pursue the object,

* See Die Praxis des Pigmentstreichens, by E. Friedlein. Munich: Published by Koenig and Hirsch.

and hope, for the sake of our art, soon to read that some ingenious brother has brought it to a practical termination.—
I am, dear sir, yours very truly,
5, Clarence Place, Ilfracombe, April 16th. JAMES MARTIN.

WHAT IS THE COST OF PRODUCING CHROMOTYPES?

DEAR SIR,—Being continually asked what is the cost of producing chromotypes, will you kindly allow me space in your valuable paper to quote my experience for the benefit of photographers generally? I will give the working of a band of tissue into cartes-de-visite, as the most easy for comparison:—

To produce 21 dozen, or 252	
cartes, one band of tissue ...	£0 7 0
One band transfer paper ...	0 2 6
Transfer collodion ...	0 2 6
Mounts ...	0 4 0
Wages for operator ...	0 10 0
Wages for spotting and mounting	0 5 0
	£1 11 0

I suppose this to be about the average quantity that will be produced daily in an ordinary studio, and I think a very easy day's work for an operator.

At the above rate the cost of producing cartes in chromotype is only one shilling and sixpence *per dozen*; and if we allow the enormous amount of 24 per cent. for waste and mishap, they are still short of two shillings *per dozen*.

If any photographer will honestly compare this with the cost of silver printing, and consider the advanced price that he could easily obtain for chromotypes, I think he will have sufficient courage at least to inquire into the supposed mysteries of carbon printing.—Yours truly,
116, Nevill Street, Southport. G. HIGGINSON.

Proceedings of Societies.

EDINBURGH PHOTOGRAPHIC SOCIETY.

THE second popular meeting of the session was held in Queen Street Hall, on Wednesday evening, the 11th inst., on which occasion a very large audience assembled to hear a lecture on Arctic exploration.

The rostrum, as usual, was occupied by Dr. JOHN NICOL, who introduced the subject by answering four questions: "What is the North Pole?" "Where is it?" "Why do people want to go to it?" and "What has hitherto prevented them?"

Some amusement was created by the answer to the second question, which the lecturer said was more difficult than the others, the Pole being, like all terrestrial things, subject to change, "here to-day and away to-morrow," only the to-day and to-morrow included, probably, thousands on thousands of years. The fact of a twenty-foot seam of coal, in which were to be seen leaf impressions, having been found within five hundred miles of the Pole, proved beyond doubt that a temperate climate had once obtained there, and equally so, he thought, that at that period the Pole had been in another place.

Arctic exploration from 1575 down to the expeditions of McClive and McClintock in 1858, was rapidly surveyed, and it was shown that till the latter date there had generally been a twofold object in view: the discovery of a north-west passage to India, and to reach the Pole; and that although the main object had, up to that time, eluded the grasp of the explorers, benefits had been conferred on both science and commerce of much greater value than anything likely to result from the finding of that which they went to seek. The various expeditions from 1853, when the discovery of the north-west passage left the Pole as the principal object of interest, to 1876, were next briefly noticed, and the rest of the time devoted to that with Captain Nares.

The lecture was illustrated by a series of transparencies from negatives taken during the cruise of the *Alert* and *Discovery*, and the pictures were exceedingly interesting, especially those depicting the manners and customs of the Eskimo, and the grandeur of the shores of the Palaeocretic Sea.

THE first out-door meeting of the season was held on Thursday, the 12th inst., the scene of operations being Cadzow Forest, near Hamilton. Special arrangements had been made with the Caledonian Railway Company, and the party left the West Princes Street Station at seven o'clock, and reached Hamilton at half-past nine. The early ride had whetted the appetite, and consequently full justice was done to a substantial breakfast, which the landlord of the Commercial Hotel had been telegraphed to have in readiness, and then they drove off to the Forest, high in hopes of a successful day.

The first halt was made at Barnclith, a most romantic group of three houses, erected in 1583, which crown a bank, rising in terraces to a height of 250 feet above the river Avon. The terraces are laid out in a quaint, picturesque fashion, and contain a number of fine specimens—if the adjective be at all admissible—of those absurdly ludicrous trees cut and trimmed and trained into the form of vases, globes, and domestic utensils generally, in which some of our ancestors so much delighted. From the outside, however, especially in combination with an old well, several fine combinations may be made, and here several plates were exposed, and then the party entered the Forest. The word forest, however, hardly conveys a correct idea of the place as it now appears. It occupies some 1,500 acres, and in pre-historic times must have been really a dense forest of magnificent oaks, under which sheltered large numbers of fallow deer and the ancient breed of the Caledonian ox, some of the descendants of which are still to be seen, and, especially the latter, are objects of interest to visitors from all parts of the country. The glory of the oaks, however, has long since departed, and all that remains are the, in most cases, hollow trunks of the largest, scattered here and there singly, and in groups of two or three, many yards apart. But although generally hollow, and of an age previous to written history, there is sufficient vitality left to annually clothe with foliage the wide-spreading though scraggy branches which yet remain, and give to the scene a kind of weird grandeur, as they link the present with the long forgotten past. On the outskirts of the forest, and close to the River Avon, stands the ruin of Cadzow Castle—or, rather, the remains of it—which is principally an ivy-covered keep, towering two hundred feet above the stream, which is here spanned by an ancient bridge, so that there is not only fine food for the camera, but plenty of variety.

Fortunately the weather was all that could be desired, just sufficiently hazy to give the much-valued aerial perspective to those who knew how to secure it; bright sunshine tempered with masses of white clouds, and hardly a breath of wind. The company were fortunate in having Mr. Annan, of Glasgow, whose private residence is in the vicinity of Hamilton, as guide, under whose charge the most picturesque places were selected without loss of time, and they soon broke up into groups, and every camera was at work.

In consequence of the picturesque richness of the ground, work went on rapidly, and by four o'clock all the plates had been exposed and several groups successfully taken, and the members prepared to drive back to Hamilton. Of course the usual comparing of notes took place, accompanied by the usual expressions of hopes and fears as to the results incident to all dry plate work, especially in the hands of those who can only indulge in an occasional day now and then. We may say that there were thirteen cameras in the field, and as a proof that the exhibition of apparatus has some influence for good, it may be mentioned that there were four of them new—one by Jonti, of Paris, one of Aird's, and two by Meagher, all of which were got under exhibition influence. There were in all one hundred plates exposed, for periods varying from a few seconds to forty minutes, and the processes represented included wet collodion, beer and albumen, uranium, gelatinobromide, Liverpool, Warnerke's tissue, and ordinary emulsion under various modifications.

Returning to the Commercial Hotel, the company sat down to dinner at five o'clock, Mr. Pantou, at the request of the President, taking the chair, and Mr. Muir officiating as Croupier. A day in the field is generally an excellent preparation for the enjoyment of a good dinner, and the present case was no exception to the rule, and mine host of the Commercial had reason to be satisfied with the appreciation of the really excellent provision he had made.

On the removal of the cloth, the Chairman said that he was glad the Secretary was not to bother them with the transaction of any business. He thought they had much reason to congratulate themselves on the large turn-out at this the first out-door meeting of the season, and hoped it might be a favourable augury of what was to follow. They had also reason to congratulate

themselves on the very favourable state of the weather, more especially as it had been so very different during the previous week. But most of all had they reason to congratulate themselves on having the benefit of the experience of their friend Mr. Annan as the guide for the day. It had often been matter of complaint that professional photographers did not take sufficient interest in the operations of photographic societies; but certainly that could not be said of Mr. Annan. They all knew how much time and attention he had given as one of the judges at the late exhibition. Some of them knew that only a week ago he had devoted a day in arranging the present excursion; and now they had seen how quietly and efficiently he had aided them in the work of this day. He had therefore much pleasure in proposing a full bumper to Mr. Annan, in the fullest knowledge that it would be heartily responded to.

The President (Mr. Lessels) then proposed the health of Mr. Pantou, who, he said, had really been the prime mover and life of the excursion, and who really had carried through so successfully the whole organisation. There were, he said, already several offices in the Society, but as they were about to remodel the rules, it might be worth considering whether they might not appoint a Director of Out-door Meetings, and if so, he was quite certain that in that office Mr. Pantou would be the right man in the right place.

Several other toasts followed, and the time passed pleasantly till 8.30, when the train was taken for the return journey. Shortly before the train started, the Treasurer, noticing the imperfect way in which the saloon carriage was lighted, disappeared, and returning shortly after, showed his usual fertility of resources in contributing to the amusement by placing on the table several packs of cards, a bag of peas to be used as counters, and two candles placed in empty castor oil bottles, by way of substitutes for candlesticks. By this means the monotony of the journey was pleasantly beguiled, and Edinburgh was reached at ten o'clock.

Thus ended one of the pleasantest of the many out-door meetings that had been held in connection with the Society.

MANCHESTER PHOTOGRAPHIC SOCIETY.

An ordinary monthly meeting of this Society was held on Thursday evening, the 12th inst., Mr. THOMAS REYWOOD, Vice-President, in the chair.

After the minutes had been disposed of, Mr. G. T. YORSTON, Mr. JAMES CALVERT, and Mr. ROBERT BANKS were elected members of the Society.

Mr. NOTON read a paper on "Oxygen-Producing Apparatus" (see page 183), and exhibited his new retort. A conversation followed, during which the only noteworthy statement was made by Mr. W. CHADWICK, to the effect that he had found the substratum of manganese for his cakes (recommended at the last meeting) quite unnecessary, the cakes, after yielding their oxygen, being removed without difficulty.

Mr. D. YOUNG exhibited some emulsion plates on which drying lines were visible.

The meeting, which was well attended, passed a vote of thanks to Mr. Noton, and was then adjourned.

WEST RIDING OF YORKSHIRE PHOTOGRAPHIC SOCIETY.

The ordinary meeting of the above Society was held at the Odd Fellows' Hall, Bradford, on Monday, the 9th inst., the meeting having been postponed a week later owing to the Easter holidays; Mr. SMITH, the President, in the chair.

The minutes of the previous meeting having been read and confirmed, Messrs. STANDFIELD and TERRY were elected members of the Society.

Mr. SACHS then read a paper—"Remarks on Studio-work."

Mr. WORMALD was of opinion that with regard to artistic feeling in photographs, some of the portraits by our best photographers were equally as good in light and shadow as the works of some of our best artists.

Mr. SMITH said there must always be some few photographers in advance of the rest; as, owing to the number of people in the profession, many perhaps had entered without any previous preparation, it was impossible that all should be equally fitted for the position, or qualified to be classed as artists.

Mr. GARRETT said that colour did not play a very important part in photography, and did not by any means constitute a work of art; and he was of opinion that if the public would give the photographer more time and a better price, he would then be better able to produce really artistic work.

Mr. E. GRAVES remarked, that it was a matter of great difficulty with the photographer to produce a different pose for (say) the twenty or thirty sitters he might have in one day, that is with the time he has at his disposal; but there was one thing he thought the photographer should avoid as much as possible, and that was the copying of other artists' productions. He had remarked that some of our leading photographers had a sort of pose of their own; indeed, almost a pose peculiar to themselves.

Mr. GARRETT said that at the Dublin Exhibition the photographs were classed with the Fine Arts, but he thought that could, perhaps, be accounted for by the fact that the photographs were considerably in the majority, a large number of photographers having applied for space for their exhibits.

Mr. COOK said that in his opinion the photographer and the artist were about equal, but, at the same time, he thought photographers had not done what they might in the way of posing.

Mr. SACHS said that the duty of every photographer should be to do his utmost to elevate his art, not merely by copying others, but by trying to excel in his own productions.

Mr. COOK showed a few photographs lent by Mr. Dallmeyer, being the productions of Mr. A. Kareline, of Nijni-Novgorod, Russia, who obtained the gold medal at the Edinburgh Exhibition, which were generally admired by the members present.

A vote of thanks was then given to Mr. Sachs for his paper, and the same accorded to Mr. Dallmeyer for his kindness in forwarding the photographs for exhibition.

The meeting was then adjourned.

Walk in the Studio.

FORMATION OF THE PHOTOGRAPHIC IMAGE.—At a recent meeting of the Physical Society, Captain Abney, R.E., read a paper on "The Photographic Image," prefacing it by a brief account of the two theories, the chemical and the physical, which are held regarding it. On the former, a molecule of bromide of silver is split up into sub-bromide and bromine, the latter of which is absorbed; and, on the latter theory, light acts mechanically on the molecule, shifting the positions of the atoms. Poitevin has done much to confirm the former of these by placing a film of silver iodide in contact with a silver plate, when he succeeded in obtaining an image both on the film of iodide and on the silver plate produced by the liberated iodine. Captain Abney has performed the following experiment. A portion of a dry plate which had been exposed was wet with a sensitive collodion emulsion of bromide of silver, and developed by the alkaline method; the films were separated from the glass and from each other by means of gelatinized paper, and were found to bear images; and the same result was obtained when the emulsion was added after exposure, development, and fixing. These experiments entirely disprove the supposition that only those molecules acted on by light are reduced. If the two films be separated by a thick layer of albumen, the lower picture develops as a negative, and the upper as a positive.

MORE MISAPPLIED PHOTOGRAPHY.—A few days ago, at the Thames Police Court, William Camerac, a foreign hawker, was brought before Mr. Lushington charged with causing an obstruction in the public streets, and wilfully exposing for sale a number of indecent photographs or pictures. Walter Gaston, a constable of the H Division of Police, said that at a quarter to one o'clock at noon on Friday, while on duty in the Whitechapel Road, he saw a large mob of persons assembled round the prisoner, who was selling photographs from a barrow. There being a great obstruction, witness requested the defendant to leave. He did so, but quickly returned and recommenced selling the photographs, which were of an indecent nature. The defendant was fined 20s. for the obstruction, and 40s. for exhibiting the photographs.

THE CENTENNIAL PHOTOGRAPH IN WINDSOR CASTLE.—In the *Ledger* of the 30th of November last we published a description of the great panoramic photograph, made by Mr. Gutokunst, of the Centennial Grounds, which carries the view from Agricultural Hall around the whole circuit of the buildings and grounds to the Observatory on George's Hill. The seven negatives for this were perfectly printed on a continuous sheet ten feet long and eighteen inches wide, an achievement unprecedented in photography, and requiring the highest degree of skill and care in the preparation of the sheet and in the manipulation of the negatives. A handsomely

mounted copy of this unique photograph was forwarded to the Queen of Great Britain by the hands of Col. Sanford, the British Centennial Commissioner; and that gentleman has forwarded to Mr. Gutkunst a letter from General Biddulph, one of the Queen's Secretaries, with "Her Majesty's acceptance" of the picture, and her thanks to Mr. Gutkunst. The photograph fully deserves this distinction, and Philadelphia may well be proud of it. It is to be placed in Windsor Castle.—*Public Ledger*.

TO ENAMEL PHOTOGRAPHS.—Take smooth glass; clean with rotten stone; polish with French chalk. With a small brush go round the edge to the depth of about a quarter of an inch with albumen diluted. Coat with collodion; dry. Take two tin dishes, fitting within each other, the outer to be filled with water, and kept warm with a spirit lamp. Put the warm gelatine in the inner one; immerse prints in. Well soak; take out each print; draw the back over the smooth edge of the dish. Lay on one of the plates, warmed slightly. Hold with the thumb and finger, and with a small squeegee rub lightly over. Let them become surface dry, and with glass put on the thin, damped backs of strong paper, and dry. Run a knife round the edge under the print to loosen from the albumen.—*Stationer*.

ANILINE WATER COLOURS.—Aniline water colours are extensively used for tinting photographs, and are also being introduced for painting water colour drawings. But as nearly all of these colours are altered by light, fade, and change, no honest artist will make use of them, unless he informs the purchaser by stamping some such notice as the following on the margin of the picture: "These colours, although pretty to look at, are good for nothing. They will soon fade."—*Scientific American*.

To Correspondents

R. D.—The proportion of pyroxyline depends much upon its quality. Some samples will make a thick glutinous collodion with three grains to the ounce, whilst others give a limpid collodion with ten grains or more. We prefer a sample of pyroxyline which gives a collodion of good working consistency with from four to six grains per ounce of solvents. As a general proportion for the salting, we like about four grains of iodide and one grain of bromide to the ounce of collodion. Take (say) two grains each of iodide of cadmium and iodide of ammonium and one grain of bromide of cadmium. Allow the collodion to stand a week after salting. This should then give good results, and improve steadily for some months. It will probably keep in good condition for a year or more. Simply iodized collodion will not keep so well. It is more troublesome to work, not readily giving such clean pictures, and is more suitable for pyro than for iron development. Altogether, we strongly recommend the use of bromide. Even a quarter of a grain of bromide to each ounce is a great improvement. 2. The preparation of pyroxyline is not difficult, but it requires care, and is occasionally not without some risk unless care be used. Take of nitric acid, sp. gr. 1.230, three ounces, and of sulphuric acid, sp. gr. 1.840, three ounces. Place these in a jar, and let this stand in a dish of hot water until the temperature of the acids is about 150° Fah. Now take two drachms of pure cotton-wool, pulled out into thin tufts, and immerse in the acids, pushing them down with a glass spatula, until the whole is immersed. Continue pushing down the cotton so as to keep it well immersed, and take care that every fibre comes into contact with the acids. Allow the immersion to continue for ten minutes. Then with a couple of glass spatulas lift the whole mass of cotton out, pressing it with the glass so as to squeeze out as much acid as possible. Then throw it into a basket of water, stir rapidly, and change the water. Continue stirring and changing until the cotton is well washed. Then pull out into thin tufts and place in a warm place to dry. The cotton will have gained from thirty to forty per cent. in weight, and should dissolve easily at the rate of five or six grains per ounce of equal portions of ether and alcohol, leaving very little residue. The chief danger arises from imperfect immersion of the cotton, or using too much cotton, which will occasion evolution of the acids, and giving off of nitrous fumes poisonous to inhale. The acids in each case spurt up sometimes on the operator's hands, producing serious wounds. It is best to wear india-rubber gloves with gauntlets to cover the wrists.

A. E.—So far as we can judge from the plans, your studio will answer well. It will not infringe Mr. Vanderweyde's patent; it trenches more nearly upon Mr. Slingby's design, but we do not think it will infringe his patent, so far as we can judge.

W. C. P. E.—A good quarter-plate or carte lens will answer your purpose best. A lens of long focus is not required for enlarging. Such a lens will also answer for lantern purposes.

B. C. BURY.—It will be quite possible to produce portraits in such a room as you describe, although, of course, it would be better if you had more light. But you will find that by the use of a white screen opposite the window you will get reflected light on the shadowed side of the sitter. It will be wise, also, to place the sitter in a position partially inclined towards the window; by this you will gain an advantage. The light through the glass door at the end of the room opposite the background will also tend to soften shadows. A sheet of tissue paper will modify direct sunshine, and render it useful.

G. M. R.—Fargler's original method (the first by which a carbon print was exposed on one side and developed on the other) was as follows:—A sensitive preparation of gelatine and bichromate of potash was spread on a glass plate, and allowed to dry. The plate was then placed under a negative, the coated side being in contact with the negative. After exposure the exposed film of gelatine was coated with tough plain collodion, and when dry immersed in warm water, this dissolved the under layer of bichromated gelatine, and the film floated off into the water, exposing the under side, the development with the warm water proceeding at that side opposite to that which was exposed and afterwards protected with collodion. The floating film had then to be lifted from the water and mounted. The especial point of Mr. Swan's process was providing a practical method of effecting the same purpose, which, it will be seen, was then difficult and uncertain.

G. WRIGHT.—Since answering you before, we have made enquiry, and find that the answer we gave is correct. You can make no conditions in enlisting; but, possessing a knowledge of photography, you would, on enlisting in the Engineers, be almost certainly placed in the photographic department.

STANISLAW LAWREN.—In reply to a correspondent recently enquiring where he might purchase lenses for a stereoscope, Messrs. Chancellor and Son, of Lower Backville Street, Dublin, write to say they can supply them.

W. ALAN ASHES, JO. VARRIE, and others, in our next. Several Correspondents in our next.

METEOROLOGICAL REPORT FOR MARCH.

BY WILLIAM HENRY WATSON, F.R.S., F.M.S.

Observations taken at Brompton, near Whitehall, 26 feet above sea-level.

Date.	BAROMETRIC PRESSURE.			TEMPERATURE (IN DEGREES).			REMARKS.
	Morning.	Noon.	Night.	Morning.	Noon.	Night.	
1	30.10	30.18	30.30	30°	30°	30°	Rain at night. Gloomy all day.
2	29.00	29.01	29.31	43	45.5	43	Rain morning and night. Foggy the rest of the day.
3	29.55	30.28	30.04	47	51.5	44	Foggy. A little rain morning and afternoon. (noon)
4	29.78	29.78	29.79	37	42	36	Fair, generally sunny.
5	29.80	29.63	29.07	36	40	41	Rain this afternoon and night.
6	—	—	29.73	—	—	34	A little sleet this afternoon.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

A PERMANENT PHOTOGRAPHIC EXHIBITION IN LONDON—THE REPORT UPON THE TRANSIT OF VENUS OBSERVATIONS.—

A Permanent Photographic Exhibition in London.—The other day we overheard a gentleman remarking how strange it was there was no permanent photographic exhibition in London. He pointed out how attractive all shop windows were in which photographs were exhibited, and mentioned the names of some dealers before whose premises a crowd of spectators was always to be found. And really it does seem singular that no one should yet have deemed it worth while to establish such an affair. At the West End about this time, when "all the world and his wife" is in town, and exhibitions and galleries of all kinds are crowded from noon to evening, a photographic collection would find, we feel assured, a very large number of patrons. In the first place there are always a large number of idlers and saunterers at the West End who find it hard to get through the day, and who soon exhaust all the well known morning "shows" that are to be seen at this time of the year. Before lunch, or during that awkward period afterwards before it is time for the row, or for dinner, there is plenty of time to spare, and if a photographic exhibition were properly organized, it would be pretty certain to be a success. Of course it would have to be arranged in an attractive manner, with photographs of all kinds and descriptions, and for this reason one firm of photographers only should not be interested in the affair. Portraits and landscapes and *genre* pictures, all might be represented, and indeed a good plan would be to make a selection of the works at the ordinary autumn exhibition. Such a series, supplemented, perhaps, by a good collection of portraits of various sizes, representing past and present celebrities, would scarcely fail to prove attractive, and we do not hesitate to say, that supposing the exhibition were located in a good neighbourhood, near the Haymarket or Piccadilly, there would be no lack of visitors. Photographs of pictures should not be forgotten, and might be drawn not only from English schools, but from those of Paris, Berlin, Munich, &c., where such things are far more prolific than with us. No doubt, too, a good many sales would be effected, and in this way a larger income realised. While, on the one hand, it is very certain that the public like looking at photographs, and would not be deterred therefrom by an admission fee of sixpence or a shilling, it is equally apparent on the other that our photographers, and especially those who occupy themselves with the production of *genre* pictures and pictorial photographs, have but very limited opportunities for making the public acquainted with their work. Such men receive nowadays but very little encouragement, for, as a rule, very few copies are sold of a photographer's masterpiece. Witness H. P. Robinson's fine combination pictures, Earl's magnificent landscapes, Blanchard's studies, Rejlander's charming art sketches, to cite but a few instances at random; and yet the returns received by these gentlemen, though by no means insignificant, are sullied together inadequate. Mr. Hubbard's picture of "Stolen Moments," which received such unqualified praise, brought so little recompense for the trouble expended, as, we believe, to discourage the author against any further attempts in that direction. It is the same with the charming landscape enlargements that photographers themselves have often admired, but which do not find a sale among the general public, for the simple reason that the general public know nothing about them. No doubt the autumn exhibition of the Photographic Society has done much to make public many works which would otherwise never have reached the outside world, but an exhibition only opened for a limited season, and when town is empty, cannot further the object to any great extent. Now that carbon printing is so far advanced that we can

produce prints of large dimensions without difficulty, there is no reason at all why fine landscape productions should not take a place on the walls of our libraries and dining rooms, and replace the engravings of more or less value that usually adorn such apartments. It is not much of an engraving that sells for two or three guineas, and for this sum the finest photographs, printed in permanent pigments, can be secured. A two or three feet picture representing some bowery nook upon the placid Thames, or a well-chosen wood or lake scene—one, perhaps, with which the owner is familiar—is certain to prove far more attractive as a wall picture, than the engravings one usually sees hanging around. But there is, as we have said, little encouragement at present given to photographers for the production of such pictures, because there happens to be no mart in which they can be exhibited to the public. If this were in existence, matters would be changed; there would be a great demand for art pictures, and the securing of these would at once become a money-making occupation. There is no incentive like that of commerce, after all. Given purchases of an article, no matter whether this is the result of a man's hand or brain, and the quality and quantity of that article are at once improved. We feel sure it is due more to want of patronage than anything else on the part of the public that photographers do not produce more art pictures. A good illustration of this is shown by the incentive to literature and art which exists with us at the present moment. Neither Germany nor France, countries far larger and more populous than Great Britain, can show such a list of authors and essayists as we can, for the reason that our journals, magazines, novels and other works are more widely patronised, and sold in far larger numbers than abroad. For every writer who gets £500 for a novel on the Continent, there are probably twenty who do so in this country. It is the same in art matters, although the difference may not be so marked. Still, of the many pictures exhibited every year at the Royal Academy, it is seldom, we believe, that a fourth remains unsold at the conclusion, while many of the artists sell several copies besides the original. Such a state of things cannot fail to give encouragement to painters, and urge them to make progress in their profession, and, as a result, we may point to the many clever young artists who are now sustaining the reputation of the English school of painting. With photography it would be the same. If more patronage were given, we should have better work and more of it. But this patronage cannot be expected unless publicity is given to the pictures that are produced, and it is to this end that we have penned these words. The public naturally like photographs; it may be seen examining the works of the camera on every possible opportunity, its interest in the art being particularly marked. Let people have more chances still, we say, and the result will be highly beneficial to photographic progress, our brethren may rest assured.

The Transit of Venus Observations.—At last the House of Commons has become impatient upon the subject of the Transit of Venus observations. The other night Mr. Childers put a question regarding the publication of the results that had been arrived at, and the First Lord of the Admiralty, as representing the Astronomer-Royal, gave what information he could upon the subject. We are glad to know that there is a possibility soon of getting to know what our astronomers and photographers did on that eventful occasion. In six weeks' time, Mr. Hunt informs us, we may hope to have the declarations of Sir George Airy before us, although some mouths must elapse before the calculations based upon the photographic records can be completed. We presume it is the intention of the Government to illustrate their report by means of some of the photographs taken, for the details would be hardly complete without such addenda. It is some consolation to know that the end of the work is approaching, for this is the first intimation we have received of such being the case.

OXYGEN-PRODUCING APPARATUS.

BY M. NOTON.*

THE next point was to find out whether a low temperature would drive off any oxygen. I expected it would, as I had frequently smelled something when drying the plugs in the oven. A plug weighing 686 grains was put into one of the old retorts, a bent copper pipe screwed into the union, and the other end connected to the small washing bottle. This at the outlet was connected to a tube for delivering the gas under water into an inverted bottle full of water. The retort was put overhead in water in a can; the temperature was gradually raised to the boiling point, but not a bubble was obtained. Tablespoonsful of salt were added at intervals, and the temperature of the solution noted till there was a boiling saturated solution; not a bubble appeared. The boiling was stopped, the retort taken out, allowed to dry and cool a little, when I found the pipe screwed into union was slack, but not so slack but that if there had been a fair evolution of gas there would have been some bubbles. The plug was taken out, and found to have lost in weight six grains. It had not changed its appearance at all, and there were no alteration in bulk. The plug was then cooked in the new machine, and gave 602 cubic inches of oxygen, being at the rate of 4.74 cubic feet per pound of chlorate. It fastened to the bottom of the retort tube as usual, or worse, as it was clean.

The next day I made another trial, leaving out the washing bottle, and carrying a continuous pipe from the top of the retort to the neck of the inverted water bottle. A plug weighing 696 grains was subjected to the heat of the salt water, as before. Very small bubbles, about one a minute, passed up into the bottle as the temperature rose; the boiling was continued for half-an-hour, and then stopped. I had about one cubic inch of bubbles in the bottle which did not stimulate the red-hot end of a bit of lighted stick just blown out, so I concluded that it was simply expanded air from the retort. The plug was turned out, and found to have lost four and a-half grains only. It was quite unaltered in appearance or bulk. I have thus got at this fact—that a dry plug is not decomposed by a heat of fifteen degrees above boiling water.

Then comes another question:—Will a wet plug give off any gas? And then, another:—What is really the temperature when full decomposition begins? These questions must stand over for the present. I am glad I have solved one.

Returning now to the machine. Knowing that a draw-

Fig. 1.

ing goes further in giving an idea of a thing than mere words, I have made an elevation (fig. 1), a plan (fig. 2), a

Fig. 2.

left-hand end view (fig. 3), a right-hand ditto (fig. 4), and a photograph (fig. 5) of the machine itself, now on the

table. In the elevation, a plug, four and a-half inches long by one inch diameter, is represented as in a retort tube, five inches long by one and a-quarter inch bore. The ends of the retort tube are convex, and a handle midway is provided for. Each of the concave cups is shown with an out-

Fig. 3.

Fig. 4.

let, but one will be sufficient. That the part of the "vice" which is usually the screw box is here made into an aerated gas burner as well, the gas and air going in at the left-hand end, the drawing-up screw working in the right-hand one.

Fig. 5.

The machine may, or may not, be permanently connected to the gas-holder; in the latter case it may, like Mr. Chadwick's, be placed nearly anywhere, only requiring a flexible tube to first connect it to the washing bottle, and from there to the top of the gas-holder.

REMARKS ON STUDIO WORK.

BY A. SACHS.*

In submitting the following remarks to your attention I trust you will excuse anything in them which may not be in accordance with your own views or theories.

We are all pretty well aware that our art is denied a place as one of the fine arts. May I ask, why is this so? Photographs can and are being daily produced which, for truthfulness, delicacy, posing, and lighting, far surpass many of the so-called works of art, with the exception that they are wanting in that great charm of all pictures, namely, colour. Photography in natural colours is of so complicated a nature that it must certainly be some years to come before it is made practicable, although I have a firm opinion that it will come to pass eventually.

But, apart from the want of colour, there is also another very great cause of our being denied admittance within the bar, and that is that the really artistic part of photography has been too much overlooked in the great desire to obtain clear, sharp photographs with plenty of definition—a quality to be admired in any picture when the adjunct, light, has been properly used. If that be neglected the results are far from satisfactory, being stiff and unnatural both in expression and lighting, and is a very just reason for refusing to recognize photographs to be considered as art-productions. Look at the works of our acknowledged leading men, and ask yourselves, are they made at random or mechanically? No; they are the results of care and experience combined with an artistic eye and taste. It is out of the question for any person to

* Continued from page 184

* Read before the West Riding of Yorkshire Photographic Society.

produce a good photograph unless he perfectly understands, and is capable of using and controlling, his light.

The subject of light and lighting pictures can never be exhausted; but, as a passing remark, I would advise all, when they see any work or photograph worthy of a place in their album as a study, to obtain it if possible, and do their best to produce results as good, or, if possible, better. There is no harm done in imitating a good thing, and it will in the future elevate our art to the front rank.

A school of photography, for the purpose of teaching and training, would, in my opinion, be a great step towards its ultimate recognition.

As to the chemical part of photography; whilst it is essential that everything should be in good order and harmonize with each other, this department is much more mechanical than the lighting of a picture. A properly-posed and lighted photograph is charming, even if the negative, chemically speaking, be not perfect; but when all are in unison we can look with satisfaction on the result of our labours.

There are so many good formulae published that I think it would be out of place to particularize any of them; they are all, or nearly all, workable, and with care and attention give good results. If you think my own formulae would be useful, here they are, although I must say that they are about the same as nearly all use.

Silver Bath.—Thirty grains in summer; thirty-five grains in winter—very slightly acid.

Developer.—Protosulphate of iron ... 3 ounces
Glacial acetic acid ... 3
Water ... 90 "
Alcohol ... 8 to 4 "

If the developer require more than that quantity of alcohol to flow freely, there is too much ether and alcohol in the silver bath, which should be boiled in order to evaporate it. I always keep a Winchester bottle of developer in hand to age slightly before use, as in practice I find it gives cleaner pictures without any loss of power.

Intensifier.—Pyrogallie acid for intensifying I have not used for a very long time, and can recommend the formula given by Mr. V. Blanchard, three or four years ago, as follows:—

Saturated solution of iron ... 2 ounces
Glacial acetic acid ... 1 ounce
Citric acid ... 1 "
Water ... 20 ounces

to which add the silver as required.

Use cyanide for fixing, as quicker and cleaner.

PRINTING PROCESSES.

There is just now an animated discussion going on about the relative value of the two printing processes—silver and carbon—for which I must refer you to the journals; but as a carbon worker I can fully endorse all that has been said in favour of that process, as to its simplicity and also as to its commercial value. Whilst fully recognizing the merits of silver printing, I firmly believe that the sooner it gives place to its rival the better stand photography will be able to take in the arts—as permanency, without doubt, is a very great advantage, telling well with the public, and at the same time gaining both honour and profit.

DRY PLATES AS SENSITIVE AS WET ONES.

BY ERNEST BOIVIN.*

THE cleaning of the glass plates should be undertaken in the first place with soda or potash, and after several rinsings in water they are rubbed with whitening, by means of a rag or tuft of cotton wool. The sensitiveness of my plates when in a dry state depends upon this alkaline

* This paper, read before the French Photographic Society, was quoted some weeks back by our Paris Correspondent; we now give it in its entirety.—Ed. P. N.

cleaning, in the same way as the success of wet collodion plates in great measure comes from a preliminary clearing of an acid character. This operation may be carried out some time previously, and then, when the plates are required for use, there is nothing to be done beyond removing the deposit of chalk with a bit of flannel, which is only employed for the purpose, and pass over the surface a camel's hair brush. Then the plates are ready to receive the preliminary albumen coating, which consists of

Albumen (one white of egg) 30 cub. cents.
Water ... 70 "
Ammonia ... 1 to 2 "

This is beaten to a froth, and then allowed to subside.

After the surface of the plates has dried again, they may be put away in a grooved box for use when convenient.

In collodionising the glass plates I prefer to use a ripe material, or, at any rate, a mixture of two-thirds new collodion and one-third old. The sensitizing takes place in a bath prepared of:

Water ... 100 cub. cents.
Nitrate of silver ... 8 grammes
Acetate of lead ... 1 gramme
Glacial acetic acid ... a few drops

It is most advantageous, I find, to expose the sensitizing bath to full sunlight for some time, and then filter it before employment; in this way it is possible to prevent any fogging or abnormal signs of development, which is a very frequent source of non-success in dry plate work.

After sensitizing, which requires something like three minutes, I proceed to wash my plates, first of all with water slightly acidified with acetic acid, and then with pure rain-water. I then cover the sensitive film—1, with a three per cent. solution of phosphate of soda; 2, with a one per cent. solution of gallic acid; then, without washing, the undermentioned preservative varnish is applied:—

Water ... 100 cub. cents.
Pure dextrine ... 9 grammes
Gum-arabic ... 1 gramme

This varnish is prepared warm, and, after the addition of a few drops of acetic acid, it is filtered through paper.

The plates thus coated are put into a drying cupboard, so that they may be uniformly and perfectly dried, and, thus prepared, will maintain their high sensitiveness for a fortnight or so. The preservative varnish itself will keep good a long time without decomposing or deteriorating, especially if maintained at an even temperature in a cool locality.

The duration of exposure varies according to the lens employed. For instance, with a quarter-plate landscape lens, an exposure of from ten seconds to one minute suffices with a diaphragm of a centimetre.

As regards the development of the image, I proceed as follows. I immerse the exposed plate in very pure water, and then pass it into another bath containing tepid water. I wash the plate for the last time, and then submit it to the action of the undermentioned developer:—

Water ... 250 cub. cents.
Gallic acid ... 1 gramme
Pyrogallie acid ... 0.3 grammes
Acetic acid ... 3 cub. cents.
Alcohol ... 3 "

Into this developer is put, the moment that the plate is immersed, some drops of a three per cent. solution of phosphate of soda, a few drops of acetate of lead of the same strength, and a little acetic acid. At the end of a few minutes the plate is taken out of the bath again, and a trace of a solution of silver (3 per cent. strength) is added to the liquid. The plate replaced in this energetic reducing liquid speedily brings forth an image in all its details, and then more silver solution may be added if it is desired to add to the vigour of the cliché.

The intensifying of the plate is undertaken in the ordi-

nary way, and the fixing is carried out with a solution of hyposulphite of soda of twenty per cent. strength. The plate is, of course, allowed to dry before it is varnished.

I may, perhaps, be permitted to say a few words upon the theory of the process which has enabled me to obtain such charming clichés of trees and foliage this summer. The albumen I employ to impart to a sensitive film an organic matter susceptible of absorbing the iodine set at liberty by the action of the light, and at the same time, to render the collodion adherent to the glass plate.

The acetate of lead in the silver bath acts in the same way as acetic acid to prevent fogging, but with the difference that the former does not exert a retarding action. By permitting the light to act upon the sensitizing bath, I am enabled to reduce the organic matters which, separated by filtration, are no longer the cause of spots and pinholes that so frequently trouble dry plate workers.

The phosphate of soda I use after sensitizing has the effect of transforming into phosphate of silver, which is very sensitive to light, the last traces of nitrate of silver remaining upon the film after washing; the latter if permitted to remain, would alter the sensitive film in a very little while. Gallic acid is the principal agent that I employ; it acts at one and at the same time as sensitizer and preserver of sensitiveness.

The preservative varnish serves to protect the iodide of silver in the film from contact with the air; it absorbs, like the albumen, the iodine freed during the exposure of the plate, and, at the same time, prevents the collodion from changing its molecular state during its desiccation in the drying chamber. The varnish after application is very easy to remove, and is at once taken from the plate by washing, especially if warm water is used for the purpose. Thus it allows the reducing or developing agent to act with all its power upon the exposed sensitive film.

The phosphate of soda and acetate of lead added to the reducing liquid augments the power of the developer something like fifty times, and, moreover, they have the effect of producing that intense brownish-green deposit which is so valuable in the production of vigorous prints.

CARBON PHOTOGRAPHY.

PROCESSES WORKED AND PERFECTED BY A. BRAUN & Co.*

3. *Direct and Temporary Transfer.*—We have seen that the adherence consists in the transfer of the impressioned pellicle on a support, final or temporary as the case may be.

A thick glass plate is made use of, which is placed horizontally between two dishes filled with cold water.

In one of the dishes the transfer paper is soaked for a few minutes. Then the impressioned image is immersed in the other dish, and allowed to remain until it becomes a little soft. Withdrawn from the water, the print is then placed on the horizontal glass, the prepared surface of the new support in contact with the surface of the image. The squeegee is passed over the back of one of the two papers, so as to make a perfect adherence, and the print is set on one side. Five or six minutes after the adherence these prints may be developed. Those that have been placed upon a rigid surface—diapositive glass, for example—should be allowed to remain for at least half an hour before being developed. The rigid surface receiving the print should be properly cleaned, without any other preparation. The water used in these operations should be as clean and pure as possible, and should not exceed 10° Cent. (50° F.). This operation should be performed in rather a cool place.

4. *Washing.*—The impressioned print, together with its support, is immersed in a bath of hot water at from 40° to 50° Centigrade (104° to 122° Fahr.). In a few moments the coating of gelatine that has remained soluble is dissolved, the first support detaches itself, leaving the image adhering to the second support, the image appearing gradually as the soluble portions of the gelatine separate

from the insoluble ones. When the print has parted with all the gelatine that has not been impressioned, it is withdrawn and placed in cold water. If the image is over-exposed, the washing is prolonged in hot water. After withdrawal from the cold water, it is well to immerse it in a solution of 1,000 parts water and 50 parts of alum, and dry immediately.

When the print has been made with a reversed cliché, and transferred to its final support, it is completely finished. This final support is not the same for direct prints and for those which require a double transfer. The reader will find further on a list of the different kinds.

For this purpose is used a glass plate placed horizontally

5. *Final Transfer.*—The print made with an ordinary cliché should be placed on a new support, to regain its true position, on two dishes, as in Chapter 3; one of these dishes contains hot water, the other cold water. The print to be transferred is soaked for a few minutes in the cold water. The final sheet is placed in the hot water and allowed to remain in until the gelatine which forms the surface commences to become slightly swollen and soft. It is then withdrawn and adjusted on the print, which has been placed on the plate, the two prepared surfaces in contact. The squeegee is passed over the back of the final paper, so as to make thorough adherence, and then allowed to dry. Avoid rapid drying of prints on caoutchouc.

After being well dried, if the print is upon waxed paper, it will leave its temporary support very readily; it suffices to raise this support by one of the corners. If, on the contrary, the print is placed on caoutchouc, the back of the support is rubbed with a small sponge soaked in benzine, and a few minutes afterwards remove as before.

All these manipulations require great care and cleanliness.

6. *Varnishing.*—When necessary we use to varnish our prints a special varnish which we can furnish to our customers. A squeegee of velvet made expressly for this purpose is soaked in the varnish, and passed very uniformly over the surface of the print, which is dried rapidly over a small gas stove. Before varnishing the prints must be first retouched.

Reversed Cliches.—We have shown the advantages, in carbon printing, of the use of reversed clichés. We will now give the mode of operating.

The cliché is made according to the methods peculiar to each atelier; it is kept a little weaker than is required, as the gelatine will have the property of slightly strengthening it. We have found that strong clichés give better results than weak ones.

The cliché is dried, and then immersed in a solution of

Water	1000 parts
Hydrochloric acid	20 "

In which it is allowed to remain until the edges commence to rise.

It is then washed with care, and dried.

The cliché is now placed on a level tripod standing in a dish destined to receive the excess of the following well-filtered solution:—

Gelatine	50 parts
Water	600 "
Glycerine	5 "

Which is poured upon the negative image, avoiding the formation of air-bubbles.

When the gelatine is coagulated the cliché is allowed to dry spontaneously, and is collodionized with normal collodion.

Ether	100 c. c. = 3½ fl. ounces
Alcohol	100 c. c. = 3½ fl. ounces
Gun-cotton	2 grammes (31 grains)

This last coating when dry is cut on the edges with a knife, and the cliché leaves the plate very readily. The negative forms thus a pellicle which is easily kept in a book.

If it is desired to replace this cliché on glass, it is useless to collodionize it after having covered it with gelatine. In this case it is placed on a perfectly clean plate covered with

a coating of gelatine containing alum. The adherence is obtained by the use of a very soft squeegee in the identical manner employed to fix a carbon print on glass.

It is well to affix on the edges strips of black paper, placed half on the glass and half on the pellicle, so as to prevent any ulterior detachment. These strips serve also as opaque borders in the printing.

The Photometer.—The photometer that we make for the use of our customers consists of a little box, the glass lid of which is furnished with a series of nine tints increasing gradually in intensity. In the centre of each of these tints is a small space completely opaque. A strip of sensitized paper is placed behind this scale of tints, and the photometer exposed to light. As soon as the tinted divisions become impressed, the opaque space will appear in white on the sensitized sheet, and opposite a number which serves to indicate a tint corresponding to the more or less vigorous appearance of a cliché.

The strip of sensitive paper is placed on a movable board, covered with osontobous impregnated with a little benzine, so as to retain the paper.

For sensitive paper we make use of the back of our sensitized pigment paper.

Before commencing regularly the printing it is well to develop a first print which, by the aid of the photometer, will determine exactly the time of exposure according to the sensitiveness of the paper.

We should remark that in developing the prints a certain time after their printing, they become stronger, and consequently should be printed a little weaker than if they are developed when just coming from the frame.

Our photometer is so easily used that we have no hesitation in recommending it to our customers.

We have given as simply and as clearly as possible the different operations of a process used daily in our ateliers by nearly one hundred employés. If we insist on the importance of our work, it is in the hope that the public will see in it an important guarantee of the correctness of the information contained in this treatise, and which is the result of observations and improvements made during a number of years.

We have not paid much attention to the careful style of our language. In offering this treatise to operators we hope that it will be useful to them in their first serious experiments with carbon photography. Moreover, we place ourselves at the disposal of our customers who might wish to see in our ateliers the different manipulations as we practise them there.

METEOROLOGICAL SUMMARY, 1876.

TAKEN FROM THE REGISTER OF W. H. WATSON, F.C.S., F.M.S.—The monthly highest, lowest, and mean temperatures observed at Braystones, near Whitehaven, during the year ending December 31st, 1876, have been as follows:—

1876.	Highest.			Lowest.			Mean.			Of all Observations.
	Mornings.	Noons.	Nights.	Mornings.	Noons.	Nights.	Mornings.	Noons.	Nights.	
January ...	47°	50°	49°	31°	31°	22°	37° 5'	40° 8'	38° 0'	38° 7'
February ...	48°	54°	50°	32°	33°	24°	38° 0'	43° 4'	40° 4'	40° 8'
March ...	50°	54°	50°	26° 5'	38°	29° 5'	39° 0'	43° 8'	39° 2'	40° 8'
April ...	53°	61°	58°	32°	40°	32°	44° 0'	51° 8'	44° 5'	48° 8'
May ...	58°	65°	63°	41°	46°	39°	45° 0'	56° 1'	48° 0'	49° 7'
June ...	75°	82°	71°	50°	57°	48°	57° 9'	64° 4'	55° 3'	59° 2'
July ...	74°	79°	69°	54°	58°	54°	61° 6'	67° 3'	59° 5'	62° 9'
August ...	78°	82°	74°	52°	54°	46°	62° 1'	66° 0'	55° 4'	62° 3'
September ...	59°	69°	67°	48°	52°	48°	53° 1'	61° 5'	49° 9'	51° 8'
October ...	60°	65°	61°	51°	40°	53°	61° 2'	55° 8'	51° 7'	52° 8'
November ...	52°	55°	54°	38°	35°	33°	43° 0'	45° 7'	42° 5'	43° 4'
December ...	53°	58°	49° 5'	28°	32°	29°	43° 5'	46° 0'	43° 4'	44° 0'
In the year...	76	82	74	33	30	22	—	—	—	—

The highest and lowest readings of the barometer (thirty-six feet above sea level) were as follows:—

1876.	Highest.	Lowest.	Day on which the highest was observed.	Day on which the lowest was observed.
January ...	30.45	29.32	15th	20th & 21st
February ...	29.95	28.93	7th	18th
March ...	29.80	28.20	18th	8th
April ...	30.20	28.62	5th	19th
May ...	30.20	29.37	8th	22nd
June ...	30.08	29.35	27th	5th
July ...	30.20	29.40	15th	7th & 8th
August ...	30.16	28.92	11th	31st
September ...	30.10	29.18	20th	5th & 6th
October ...	30.14	28.79	31st	11th
November ...	30.20	29.15	1st	16th
December ...	29.97	28.26	9th	4th
In the Year ...	30.45	28.20	January 15.	February 6.

The following table gives the number of fair days, number of days on which rain fell, number of fair days bright, and number of fair days gloomy:—

1876.	Fair Days.	Days on which Rain fell.	Fair Days Bright.	Fair Days Gloomy.
January ...	14	17	3	11
February ...	5	24	3	2
March ...	12	19	5	7
April ...	14	16	7	7
May ...	23	8	7	6
June ...	20	10	15	5
July ...	22	9	18	4
August ...	17	14	13	4
September ...	16	14	10	6
October ...	18	18	7	6
November ...	18	12	11	7
December ...	6	25	2	4
In the Year ...	180	186	111	69

The monthly mean temperatures of the year 1876 compared with those of the previous year furnish the following numbers; the mark + of course expressing so many degrees higher than in 1875, the mark — expressing so many degrees less:—

1876.	Mornings.	Noons.	Nights.
January ...	5.1° —	3.9° —	4.2° —
February ...	2.6 +	2.8 +	3.4 +
March ...	0.3 —	1.2 —	0.6 +
April ...	3.4 —	0.2 —	0.5 —
May ...	6.4 —	0.3 —	8.1 —
June ...	1.4 +	2.9 +	0.1 —
July ...	3.9 +	3.3 +	2.2 +
August ...	2.3 +	1.4 +	1.9 —
September ...	3.9 —	0.5 +	6.5 —
October ...	4.8 +	4.8 +	8.0 +
November ...	2.4 +	2.7 +	3.3 +
December ...	2.9 +	3.9 +	8.1 +

Comparing the number of fair days in the year 1876 with the number of days on which rain fell, we find the days on which rain fell exceeded the fair days by six, while the fair days bright exceeded the fair days gloomy by forty-two. The fair days in 1876, compared with those in 1875, show a difference of three,—more in the former (1876). Further comparisons may be made by referring to the summaries for 1874 and 1875. PHOTOGRAPHIC NEWS, vols. xix. and xx., pages 93 and 161.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—At the next meeting of this Society, on Thursday, May 3rd, in the rooms of the Society of Arts, John Street, Adelphi, a paper on "Photographic Difficulties" will be read by Mr. F. York.

HEATED AIR INSTEAD OF OXYGEN IN THE LIME LIGHT.

MEANS of producing artificial light of good actinic quality at a moderate cost, without risk of explosion or other danger, must always interest photographers, and many and various experiments made from time to time have been brought under the attention of our readers. The oxyhydrogen light has of course satisfied the condition of efficiency; but besides the cost of oxygen there has been the greater objection of risk in its preparation, storage, and use. Mr. Woodbury has recently been good enough to bring under our attention the result of some experiments, by which he hopes to obtain a light, in all respects efficient for lantern purposes and for enlargement, in which, whilst obtaining the brilliancy and the purity of incandescent lime, he dispenses entirely with oxygen in obtaining it.

Mr. Woodbury does not claim to have invented a new thing, but he has made a valuable application of an existing thing. Some of our readers may be familiar with the Fletcher blow-pipe, in which a jet of heated air, inside a gas jet, emerges at the same orifice as the gas, into the flame of which it enters, producing an intensely hot concentrated flame. This constitutes the Fletcher blow-pipe. The air-pipe is connected with an air-bag, sending a stream of air through it, finally entering a spiral tube, which twines round the gas-burner, both being heated by a Bunsen burner underneath. The intense jet to which we have referred is made by Mr. Woodbury to play upon a lime cylinder, by which is produced a concentrated flame of very intense brilliancy and pure actinic colour, admirably suited alike for the sciopicon or other magic lantern, and for photographic enlarging purposes.

The apparatus is neither complicated nor costly, and there is no complexity or difficulty in the working. The one point which Mr. Woodbury is still anxious to improve is the lime cylinders, which have the usual tendency to crack, and eventually fall into pieces. He is experimenting to secure some improvement here, and should he succeed we shall bring the matter again under the attention of our readers. In the meantime, the gain in simplicity, cheapness, and absence of danger is sufficient to recommend the improvement to all interested in the use of such lights.

FRENCH CORRESPONDENCE.

RECTIFICATION.—A CAUTION TO WORKERS OF EMULSION—DETONATION OF EMULSION COLLIDION—M. JANSSEN'S SUN RECORDS—IMPORTANT RESULTS—PHOTOGRAPHY AND THE PREFECTURE OF POLICE—SOCIAL GATHERINGS—THE VANDERWEYDE ILLUMINATING METHOD, AND THE NEW ELECTRIC LIGHT.

I WOULD ask permission in the first place to repair an error which slipped in my last letter. In giving the for-

mula for the collodion employed by M. Boivin, I wrote water for ether, which makes the collodion a very fantastic novelty. The formula should stand:—

Ether...	...	60 cub. cents.
Alcohol...	...	40 to 50 "
Pyroxiline (friable)...	...	1.50 grammes
Prepared at a high temperature.		
Bromide of zinc or ammonium	...	1.50 grammes
Bromide of uranium	...	1.50 "
Chloride of barium...	...	1.50 "

I said that after having coated the plate with the emulsion collodion, the latter is covered with a preservative, to render the films capable of use as dry plates. Of the many preservatives that may be employed for the purpose, M. Boivin has chosen one which not only gives good results, but which is also far from costly. Its basis is emetine, and may be easily obtained by boiling some ipecacuanha root in distilled water. A porcelain utensil is employed for the purpose, and five grammes of the root suffice for one hundred grammes of water. The roots are first of all reduced to powder. The liquid thus obtained contains emetine, sugar gum, gallic acid, and a resinous substance, which is precipitated by cold, and remains attached to the paper on filtering. The preservative, which will keep good for a fortnight, is equally good for application to emulsion collodion as to simple bromized collodion.

M. Boivin has discovered, by accident, a singular property which the emulsion collodion that he makes use of possesses. To study the structure of the impressioned film and the vascular tissue that is formed, he placed a film close to a lighted lamp, in order to examine the former particularly. Unfortunately, he approached the film too closely, and produced an explosion, to the great astonishment of the investigator; the film disappeared from the plate entirely, the latter being highly charged with electricity. The explosion had the same sound and intensity as the explosion of a small percussion cap, and was accompanied by a flash like that of an electric flash.

M. Boivin, to continue the experiment, at once detached some fragments of dry emulsion collodion from a plate, and approached them to the lamp. Another explosion, accompanied by a second vivid flash, was the result. My friend proposes to still further investigate the matter, so as to arrive at the rights of this singular phenomenon.

M. Janssen, at the last meeting of the Academy of Sciences, exhibited two photographs of the sun, obtained at the observatory at Meudon, which were peculiarly interesting. The pictures showed that a very important spot of some kind had suddenly formed upon the sun on the 14th and 15th April. An image taken at eight o'clock in the morning on the 14th inst. (with the instruments of which I have spoken in a former letter) showed the sun's disk perfectly free from spots, and as the diameter of the picture measures 30 centimetres, and the granulations on the surface are very clear, there is clear proof that the solar hemisphere, then turned towards the earth, was at that moment quite free from spots. But in the cliché executed on the day following—that is to say on Sunday, the 15th April—at the same hour, there was to be seen in the southern hemisphere, near the line of the poles, and close to the centre of the solar disk, a patch 2 centimetres in diameter covered with spots. The biggest of them presented a size varying from 15 to 20 millimetres, with the penumbra of figures in a very disturbed condition.

Now, what is curious about the matter is, that we are now at the time of the year which corresponds to a minimum of solar spots, and this epoch is attributed to a repose of the photosphere. But since M. Janssen has been engaged in making a daily photograph of the sun he has been in a position to observe that minor spots are produced, which, however, rapidly disappear. M. Janssen was desirous of securing upon the following days a series of views of the phenomenon which would have permitted him to follow its course until its disappearance. Unfortu-

nately the very bad weather interrupted his observations. In any case this example of solar photography has shown how right the eminent astronomer is in the course he has taken in insisting upon the utility of having recourse to photography, and getting the art to assist in securing records, the value of which can hardly be exaggerated.

Some very curious experiments have been made this week, by the photographic staff of the Prefecture of Police, respecting which I have several times spoken in the columns of the PHOTOGRAPHIC NEWS. The trials were in reference to a system of telegraph apparatus which permits of instantaneous transmission to a distance of portraits of any individual who may be wanted by the police. A sketch, made either from life or from a photograph, which has been procured, may be transmitted anywhere by the wires. It seems that the experiments, so far, have been very satisfactory, and I shall return to the subject shortly and supply my readers with details.

Another dinner has taken place among photographers concerned in the *Chambre Syndicale* of photography in Paris, at the Palais Royal. Subjects of professional interest were discussed during the fraternal gathering, and various projects were mentioned having for their object the drawing together of photographers more frequently. Another reunion is shortly to take place, but this time on a more extended scale, and I am glad to say under the roof of your humble servant. I shall have great pleasure in giving the readers of the PHOTOGRAPHIC NEWS an account of the affair.

During a visit which he was so good as to pay me, M. Vander Weyde explained to me the system of lighting studios which he has elaborated, and which has been spoken of in this journal some time ago. Some public trials are being made in Paris of a new description of electric apparatus, and M. Vander Weyde believes it possible by the aid of this to perfect his invention. I allude to the electric candles of MM. Denayrouse et Jablochkoff. The trials of these have been crowned with the complete success. At this moment the Grand Magasins du Louvre are lighted up by this invention. MM. Denayrouse et Jablochkoff pass an electric current through a plate of kaolin containing in the path of the fluid a conducting matter, which, on being consumed, heats the plate to such a degree that it becomes incandescent, and becomes in this way a conductor itself. It emits a most intense light, one, too, which is perfectly stable. As the kaolin is not consumed, the light is not interrupted. Such is the candle in question, but this is not all. The electricity may be disposed in such a way as to pass to a number of branches, and in this way the light can be distributed throughout a town, and this lighted up in the same way as gas is distributed nowadays.

It seems to me that the invention may well be combined with M. Vander Weyde's system of lighting, for the benefit of photographic studios.

ERNEST LACAN.

SIMPLIFICATION OF THE CARBON PROCESS.

BY H. BADEN PRITCHARD, F.C.S.

I AM induced to send you a few words upon the subject of carbon printing, for the simple reason that some gentlemen, who recently honoured me with a visit of inspection here, believe that the *modus operandi* I am employing for portraiture has something to recommend it. It is, however, very likely not new, or may, for aught I know, have something in common with Lambertype, Chromotype, Sawyer-type, &c., of all of which processes I am profoundly ignorant.

Wax and collodion are universally employed, I believe, in carbon printing, but some people use them one way and some another. Instead of waxing plates and then collodioning them, I find it simpler to do no more than apply wax, so far as the glass plates are concerned. After my tissue is printed, and before dipping each piece into cold

water (prior to development), I fix it upon a flat piece of wood, and apply a collodion film. A simple wood frame, like that of a slate, but having rubber fitted round the margin, is doubled over the board to keep the tissue in position, and prevent the collodion touching the extreme edges of the tissue. The thumb keeps the frame pressed against the tissue till the surplus collodion is poured off. As soon as the collodion is set the tissue is put into water; the greasiness of the collodion surface is washed off while the tissue soaks, and I then apply the print to the waxed plate, and develop in the ordinary manner.

A more even expansion of the gelatine is thus ensured, and there is no risk of losing any of the delicate portions of the picture. The tedious operation of collodionizing and washing a whole series of glass plates is avoided, and the coating of the pieces of tissue just before development is very easily and rapidly accomplished.

While on the subject I would point out to your readers the importance of distinguishing the phenomena of reticulation and insolubility, now that the warm weather is coming on; the former is to be subdued in a very great measure, the latter cannot under any circumstances be remedied.

War Department, Woolwich, 10th April.

BACKGROUND PAINTING.

BY NELSON K. CHERRILL.

I HAVE tried a plan of mixing the colours for background painting which has succeeded so very perfectly, and is at the same so exceedingly simple in practice, that a note of it may prove of some value.

I used Vandyke brown as the dark colour in preference to lampblack, and common whiting with the white. The Vandyke brown I purchased in a tin "ground in water." Large quantities of it in this form are sent out to these colonies, where it is used chiefly in making a stain for the interior woodwork of the houses. The tin being opened, the colour is as stiff and solid as cheese, and can be cut out with a strong knife. I cut out a lump of this colour and place it on a slab of glass, practically on a fifteen by twelve plate laid on the bench. Along with the colour I place a handful of whiting, and then add a little water. I now mix the white and brown together, using the flat side of a large chisel as a spatula. The mixing requires to be very thoroughly done, and is best if done in detail, i.e., a very little at a time. The tin colours being mixed (water enough being added to bring the mixture to the consistency of thick cream), they are placed in a bason, and the operation is repeated, using, as near as may be, the same proportions of brown and white. When the bason is full, the "tints" for the background may be made up. I take that which is in the bason for the darkest tint, and dilute some with more white for the lighter; for the actual lightest tints pure white may be used, as by the method to be described it will not come out white in the result. To make the colour so prepared stick, I use starch, which I find has every useful quality. I use three or four large, i.e. piled-up, tablespoonsful to a pint of water, mixed cold, and then well boiled up. When well set, I add another pint of water, cold this time, stirring briskly all the time. About one part of this starch mixture to three or four of the colour mixture forms the consistency of the paint; it may be, however, thickened or thinned within very considerable limits without detriment. I have not as yet tried how little starch will do, but it is a very small proportion, much less than might have been imagined.

To apply this colour to the background, if it necessary first of all to wet the canvas all over; this is best done with a wide plasterer's brush; when the canvas is quite saturated the painting may be begun. I prefer laying the darks on first, slushing the colour on broadly and thick with a wide brush; the canvas being wet, the paint goes on with an admirable smoothness from the first. When the darkest parts are in, put the next in order, and so on till

the very lights, which may be, as before mentioned, done with quite white colour. When the whole canvas is laid with the colour, it is ready for *brushing*, which is an important part of the process, as by it the tints are so perfectly bleended one into another that the effect when finished is as smooth and soft as can be imagined. A large, stiff clothes brush, fixed crossways on the end of a long handle like a garden rake, is the best form of brushing apparatus. The newly-painted background may be attacked with a weapon such as this, and vigorously brushed in all directions, due regard being had to the effect desired. When dry, the background will have a pleasant, warm colour, far preferable, in my opinion, to the cold grey obtained by the use of lampblack or "drop black" such as is commonly recommended.

The directions given above refer to the production of merely "*gradated*" backgrounds, but the same principles may be adopted to more elaborate works. The colour does not dry on the canvas, even in very hot weather, in less than two or three hours, so that ample time is given to put in quite an elaborate design if such should be required. Moreover this process has a very great advantage in one respect, namely, the work when dry can be touched and retouched as many times as needful without trouble, and the colour used in these retouches will dry on the old, and come to its proper shade without any trouble, and without so far as my experience goes, any danger of the edges of the new touches showing stains or joining marks. To retouch the background slightly, it is not necessary to wet it again, as the colour will work over that which is already on the canvas quite comfortably, if much has to be done, however, it will be well to wet it all over before starting, in this case the water must be applied from the back.

I find that if the paint be kept four or five days after mixing a sort of fermentation sets in, and the starch begins to decompose, when this is the case the whole mass becomes filled with minute air-bubbles, and the smell given off is rather unpleasant, in this state, however, the paint works quite as well, and if anything rather more smoothly than when fresh mixed. The smell does not remain after the background is once dry.

I think that photographers who have been doing their backgrounds with the crayon process, would be pleased if they would follow out the plan I have suggested. It is at any rate worth a trial.

Christchurch, N.Z., January 6th.

CARBOLIC ACID IN PHOTOGRAPHY.*

It has already been stated by M. E. Friedlein, at a meeting of the Vienna Photographic Society, that the addition of small quantities of carbolic acid to the bichromate sensitizing bath is of advantage. Recently M. Friedlein has again referred to the subject, and points out the advantage of employing the same acid in the case of all operations connected with gelatine. Especially is carbolic acid of use in the Woodbury process, this gentleman affirms, for without the addition of this preservative the gelatine solution will scarcely keep good a couple of days in mid-summer, and has been known to decompose in a day, with the evolution of noxious gases.

One per cent. of carbolic acid added to a thin gelatine solution, as in the case of the Woodbury process with the gelatinous ink, is sufficient to preserve the gelatine mixture in good condition for months, even in an open vessel, summer and winter alike. The only change that will then take place is the hardening of the surface through evaporation. As in the carbon process, especially in summer, and when the drying operation takes a long time, many defects occur through the decomposition of the gelatine, it is well to add to the bichromate bath a little carbolic acid. In this way the operator is assured against defects, and the

sensitized tissue may be preserved good for a week. The smell of the acid is, after all, but a slight drawback compared to the benefit it confers. In a work on the practice of carbon printing, the following formula for making up the bichromate formula is given, viz:

Bichromate of potash	30 parts
Water	800 "
Fluid carbolic acid	1 "
and in summer			
Glycerine	1 to 6 "

The carbolic acid is prepared by rendering fluid 5 parts of the crystallised acid by standing in hot water, and adding one part of warm water.

ERRORS IN THE TRANSIT OF VENUS PHOTOGRAPHS.

BY M. A. ANGOT.*

I HAVE already remarked upon the several causes which may modify the dimensions of photographic images obtained by means of astronomical lenses. The results are to be explained by the ordinary laws of diffraction, and are quite in accord with these. I crave permission to submit the results of my further research upon the photographs of the Transit of Venus.

In making photographic observations of the passage of this planet, two different objects were in view:—1, To measure the parallactic effect direct—that is to say, the difference in the apparent positions of Venus seen at the same moment at two distant stations; 2, to determine photographically the instant of contact. The first operation belongs properly to photography; the second was undertaken only to support the ordinary astronomical observations, and will form the subject of an early communication.

1. *Direct Measurement of the Parallactic Effect.*—The parallactic effect may be measured in two different ways: (a) by the angle of position, or, in other words, by the angle that is formed every instant by the line of centres of Venus and the sun with a fixed direction—that of the equator, for example; (b) by the distance between the centres of the two luminaries.

(a) Measuring the angle of position, according to former experience, one might expect to obtain an image of the sun larger than the geometric image, and one of Venus, on the other hand, smaller. The difference varies, and in notable proportions, with the sensitiveness of the plate, the duration of pose, the intensity of light, and the degree of transparency of the atmosphere. If the optical system which is employed does not distort the images in an irregular manner, the position of the centres of the two luminaries will not be in any way changed; and, theoretically, the measurements of the angle of position should yield trustworthy results. But, unfortunately, in practice we meet with very great difficulties in obtaining, with that degree of exactness demanded for calculation, a fixed direction to serve as the origin of angles of position. The American expeditions are, to my knowledge, the only ones which have sought to solve the problem; and it will be necessary to admit the publication of their results in order to learn their method of procedure.

(b) Measuring the distance between the centres. The position of the centre of the two luminaries is not modified, as I have pointed out, by the phenomenon of diffraction, which introduces into the image an optical system supposed to be perfect. The measurement of the distance between the centres should, therefore, theoretically inspire every confidence. So far experience seems to show that the dimensions of apparatus and the method of operating chosen at the French stations will give us the distance between the centres of the luminaries with that degree of exactness necessary for calculating.

But there is in the process a difficulty of the same nature

* Photographisches Correspondenz.

* Presented to the Academy of Sciences.

as that which we have noted in the preceding; it is the determination of the angular value of the images. The focal images are measured in millimetres, and in order to be able to compare the image obtained at the different stations, it is necessary to know the angular value of a millimetre placed in the focus of each instrument. It is possible, however, to obtain this value in several different ways: either by photographing a luminary—the sun, for instance—at two different and known times, the apparatus remaining fixed in the interval, and comparing the metric distance of the two images with the interval of time that separates them; or by placing in the focus of the instrument a thread micrometer, or glass plate with scales, and noting the time that a known luminary takes to pass through a given space; or again, by photographing the micrometer of a meridian lens, serving as collimator, &c.

There is, finally, a last process which, at first sight, appears to be very trustworthy, but which, in practice, gives rise to many material errors. I have shown, in operating upon objects uniformly lighted, having rectilinear margins, and dimensions very much larger than the zone of diffraction, that the augmentation of the image of a luminous object is equal to the diminution of that of the obscure object in the same circumstances. The sum of these dimensions is, therefore, constant, and equal to that which it ought to be if the image were formed simply according to the laws of optical geometry. If always exactly the same for the sun and for Venus, the diameter of these two luminaries, though varying in one image and another, will thus give a constant and unvarying total; and this total might serve as the factor of reduction for the purpose of comparing among themselves the images of different stations; so that it would suffice, under the circumstances, simply to determine exactly the angular value with one instrument.

Unfortunately, it is impossible to rely upon the constancy of the factor for several reasons:—

1st. The diameter of Venus is far from being of considerable dimensions taken in relation to the different zone. Theory shows, therefore, that the diminution of the diameter of Venus is not the same as that which takes place in a rectilinear margin, the sun having a curve slight enough to act sensibly as a rectilinear margin.

2nd. The luminous intensity of different points in the sun is not at all uniform; it decreases rapidly towards the limb, by reason of the physical nature and convexity of the luminary. Venus is projected upon a point on the sun much more luminous than the margin, but the intensity of which is always varying as the planet moves over the surface of the sun. The augmentation of the sun is, therefore, different to the diminution in Venus, and the sum of their diameters varies with all the conditions of the experiment.

These conditions depend materially upon the sensitiveness of the plate, the duration of exposure, and the transparency of the atmosphere at the moment when the photograph is secured, and it would be impossible to keep count of these.

These provisions have been confirmed by experiment, and, what is more, the measurement of the images of the Transit will afford evidence of these causes of error, and demonstrate that to determine the angular value of each instrument it will be necessary to have recourse to one of the other methods above described.

PHOTO-COLLOTYPE PRINTING.

BY M. T. H. VOIGT.*

PRINTING in greasy ink has received some marked improvements from the hands of M. Albert. In the under-mentioned formulae, which are those that gentleman employs, all the substances of no use which we find in the former processes are put on one side, and it is only necessary to pay attention to the manipulations in order to arrive at excellent results.

Formula for the First Film.

Gelatine, dissolved at a mild temperature in 270 grammes of water ... 15 grammes
Bichromate of potash, dissolved in 270 grammes of water ... 34
Albumen beaten to a froth ... 210

The liquids are added one to another, well mixed, and filtered while warm. Polished glass plates are covered perfectly with ammonia, and put upon a lattice of wood, then put upon a stove and warmed. The plates are then covered with the above mixture of albumen and gelatine, a flat brush being used for spreading the liquid. In applying polished instead of unpolished iron, as I have recommended, the film to be applied must be a thin one. The plates are dried at a temperature of 35° Reaumur. The mixture for the first film may be preserved for some time. In heating, it becomes an opaline jelly, which must be warmed and filtered before it can be employed; but in doing this the operator must be careful not to go beyond 40° Reaumur, because of the albumen in the mixture. As soon as the film has dried it is covered with a cloth or piece of velvet, and the plate exposed to sunlight from the back. Hence the plate is put a Vogel photometer, in which is placed a sheet of paper coated with the same mixture as that upon the surface of the plate. The exposure is prolonged until the photometer marks No. 12 on the scale. The plate is then plunged into cold water for an hour, and it is finally rinsed in cold water and allowed to dry spontaneously.

Second Film.

Gelatine, dissolved in 720 grammes of warm water ... 90 grammes
Isinglass, boiled in 360 grammes of water 45
Bichromate of potash and ammonia, of each equal parts, dissolved in 180 grammes of water ... 45

These three solutions, well filtered, are mixed and warmed to 42° R. before being applied to the already coated plates.

The second film may be prepared a long time in advance, but the plates once dry will only remain in a good condition for some days. They must be employed and washed as soon as possible, after which they will preserve for years the property of taking ink.

I will indicate a very excellent formula for the second film, proposed, I believe, by my compatriot, M. Obernetter, to whom we owe a great many photographic improvements. Albumen, to the extent of 150 grammes, is beaten to a froth, as much water and bichromate of potash (of each 150 grammes) being gradually added during the operation. As soon as the mixture has been made, there are added 30 grammes of ammonia, which is done carefully; after standing for some moments, the liquid may be filtered through a bit of flannel. This mixture will keep good for years; indeed, it improves by keeping.

The plates are first of all covered in a cold state with this mixture, then dried by being subjected to a gentle heat. They are then exposed to light from the back in the manner above indicated. After washing, they are covered with a second film.

A drying box of wood is divided into two compartments by a thin sheet of sheet iron, under which pass some tubes leading the heat from a furnace. In this way there is produced in the upper compartment a temperature of about 50° R. Into this upper compartment is put upon the sheet-iron diaphragm an iron tripod, and the door is closed with a tuft of cotton wool coloured yellow, so as to absorb the moisture produced by the desiccation of the plates. This drying apparatus, with some modifications, is that generally employed, only the tripod is ordinarily replaced by rings of iron, the position of which is altered by means of screws. The rings are so fitted that they may be approached or distanced from one another according to the dimensions of the plates.

The tube through which the smoke and heated air

pane may be replaced by a gas stove or petroleum jet under the drying box. A square opening, closed with yellow glass, which allows one to follow the drying of the plate, is fitted to the upper part of the box, which is also pierced for a thermometer to note the temperature of the apparatus.

The plates, when dry and cold, are exposed to light under a negative in the manner already described. The printing frames differ somewhat from those in general use. The negatives and the sensitive film of gelatine are pressed one against the other by the wooden corners, the springs not giving sufficient pressure to assure perfect contact and printing. The sides and end are raised to permit one to superintend the printing, and to avoid the introduction of light from behind. The bottom of the frame is formed by a wooden shutter, and the whole is put into a shallow box.

When the plates have been printed, they are put into a metal bath full of water, where they are allowed to remain, taking care to change the water from time to time, until the printed gelatine has completely lost its yellow colour. If the water is frequently changed, the plate will have been sufficiently washed in two or three hours.

As soon as the plates curve out of the water, they are washed with care under a stream, and they are then dried by pressing upon them with the hands some sheets of blotting-paper. They may at once be inked and employed for printing copies, but if a large edition of pictures is required, then it is best to let the plate remain in its present condition for a day or two.

Recently it has been thought necessary to have special presses for this kind of work. At Munich numerous experiments were made with the roller press, but it was soon found to be unsuited for the purpose. These presses are constructed like the cylinder presses, in which the steel plate is set in motion without being sustained underneath, the only difference being that the rollers were covered with india-rubber. After pulling a print, it was necessary to lift out the plate, ink the roller, put it back between the cylinders, and cover it with flannel or with a sheet of rubber, and go through the printing process once more. Besides the risk of breaking the plates, the process is beset with the inconvenience that two persons are required to manipulate the press, while at the same time but very few prints are pulled in a given time. Besides these presses, that of M. Roderer is also employed, with which the printing goes on more rapidly and easily. This press is a cheap one, but the roller, as also the whole of the machine, being of wood, it soon wears out.

The so-called star press (of Munich), employed by MM. Obernetter and Gemeser, fulfils its object admirably. It is constructed of stout woodwork, with rollers and levers of iron. It is easily worked, and wears well.

The Sutter presses, notwithstanding their high price, are preferable for collotype printing to all the others, by reason of their being constructed of iron. They should have double frames. Upon one of these frames is fixed a sheet of paper or tin, cut to the size of the print that is to be printed; or four bands of thin metal may be arranged so that they form a frame-work that can be opened out or contracted according to the dimension of the image to be obtained; the second is covered, as in the lithographic press, with thin leather. If we suppose that the plate, before being placed in the press, has been properly inked with the roller, the first frame is put over it to preserve the margins of the print white and clear; then the paper is put upon the printing block, and the whole is gently passed through the press. The amount of pressure is first of all regulated, the same being rather less than that exerted in lithographic printing upon stone. Thanks to the modifications we have indicated, little difficulty is felt in working the collotype process in lithographic establishments.

(To be Continued.)

A NEW PROCESS OF HISTOLOGICAL STAINING FOR MICROSCOPIC SUBJECTS.

BY FRANCIS ELIZABETH HOGGAN, M.D.

THE tissues to be stained are principally membranes or soft sections, which may be either fresh, frozen, hardened in alcohol, or hardened by the picric acid and gum process; but such hardening agents as the chloride of gold or any chromate whatsoever are inadmissible. The colouring agents required are: 1, a one or two per cent. solution of perchloride of iron in distilled water or alcohol (tincture of steel); 2, a solution of similar strength of pyrogallio acid in water or alcohol, the latter fluid being preferable in both cases. The section or membrane to be stained is first treated for one or two minutes with alcohol; the iron solution is filtered upon it, allowed to remain for a couple of minutes, and then poured off. The pyrogallio acid solution is then filtered in a similar way upon it, and in the course of a minute or two, the desired depth of staining having been obtained, the tissue is washed and may be mounted, in the usual manner, either in glycerine balsam, or varnish. The nuclei and nucleoli will be found coloured black, and the cell substance will also be coloured more or less, according to the age and other conditions of the cell. A bluish tint may be given to them by washing the section with an alkaline water; the household water of London, containing lime, is suitable for this kind of tinting. This process is especially useful for photographic purposes, and to those who can only work with the microscope in artificial light, the definition being very clear and distinct. It is probably the best process for staining silvered preparations, as it has no effect on the black lines, while it makes the nuclei very distinct. I have advised that the solution be filtered upon the preparation. This, although unnecessary with clean fresh solutions, obviates any chance of foreign matter becoming deposited on the preparation. It is easily effected by taking a piece of blotting-paper about two inches square, folding it twice, and pouring into one of the cavities thus formed about a teaspoonful of either solution, or more, according to the size or number of the materials to be stained. The whole process is speedy, simple, and permanent. The staining may be accomplished in five minutes, and the staining materials can be bought at any country druggist's shop. The filtering paper should be held with forceps to avoid staining the fingers, as the stain is difficult of removal except with the bicarbonate of potash.

THE CARBON PROCESS SIMPLIFIED.

BY R. JASTRZEMSKI.*

THE carbon prints that were first exhibited awakened in our breasts the most sanguine expectations. Unfortunately, failures and defects have arisen in the practice of the process which have rendered this interesting printing method almost impracticable for general use, while its complicated nature, compared to silver printing, is also a material point to its disadvantage. It has been my endeavour to simplify the process as much as possible, and to obviate the source of error as much as possible.

One of the great disadvantages in the practice of carbon printing is the coating of so many glass plates with collodion; not only is a suitable space required for it, but, moreover, the ether vapours are decidedly noxious to one's health. In the same way the preliminary coating of the plates with wax by the aid of a benzole solution is a very disagreeable operation, and the rubbing of the glass surface with wax is a barbarous one. By the aid of the simplification which I have imported into the process, and which is the result of many repeated experiments, I have rendered the waxing of the plates altogether unnecessary, for this coating can be put on much more advantageously at the tissue factory itself.

If the tissue itself is coated with collodion under certain conditions, there accrue therefrom many advantages.

* *Photographic Correspondent.*

1. The waxing of the plates is in the first place avoided, as well as the collodionising of them. The finished picture, too, easily comes away from the glass.

2. All tendency to reticulation (by reason of the tissue becoming horny) is avoided when the surface of the material is kept together by means of a film of collodion. Of this one may easily be convinced by coating a piece of tissue, which otherwise shows the defect, with collodion. The operator will be perfectly surprised how clean and free from defects the image will be developed, whereas the same tissue which has not been treated by my method affords pictures that are not to be criticised. By means of the improvement I suggest, the pigment tissue may, indeed, be kept in a good condition the whole summer through.

After essaying a series of methods, I found the following to be the most successful. A piece of pigment tissue is stretched by its four corners by means of pins upon a board, and then collodion (in its normal condition, and about one and a-half per cent. strength) is applied in the same way as in coating a plate. When the collodion is half set it is taken from the board, and rapidly dipped into a pan of water and moved to and fro until all appearance of greasiness has disappeared, when it is allowed to dry upon a slanting board. After it is perfectly dry, the surface is rubbed over with the well-known wax solution (wax-resin-turpentine) in such a manner that nothing, however, remains behind. This coating must be perfectly dry before the tissue is employed. Prepared in this way, the tissue may be sensitized on the day following; or, if permitted to remain in its unsensitized condition, it will keep good for an indefinite period. It is evident, therefore, that tissue thus prepared could be purchased ready for use.

The manipulations connected with the process are the following. The tissue in the condition I have mentioned is sensitized in a solution made up of—

Bichromate of potash	4 parts
Carbonate of soda	1 part
Water	120 parts.

The tissue is dipped bodily into the solution, and permitted to remain in the liquid for three minutes. The tissue, after drying, is put into the printing-frame and exposed in the ordinary manner; it is then put into cold water in the usual way, and put upon a clean glass plate, the superfluous water being expelled by the aid of a strip of cardboard, instead of rubber squeegee, which is used very energetically. It is well to put the plates to be developed one upon the other with sheets of filter paper between, and allow them to remain, weighted to a certain degree, for about half-an-hour—rather longer than shorter—and in developing it is advantageous to begin with very warm water, the paper backing not being removed until it will leave on the touch of a finger, and strips off the surface, when it is carefully lifted off.

After complete development the image should be permitted to remain for half an hour in a solution of alum, when it is rinsed and put on one side to dry. The transfer to paper takes place in the ordinary way, drying by artificial means being avoided.

The retouching of the pictures is best done by the aid of pigment dissolved in luke-warm water to which a few drops of acetic acid have been added. If there is much to do upon the pictures, or the glossiness of the surface is interrupted in patches, a coating of varnish may be given, which heightens the effect, and also shields the print against moisture. Only in this case care must be taken to employ a varnish so thin that it will not interfere with the surface of the picture, while at the same time it will bear scratching.

I may remark that in the sensitizing bath I do not employ, as may be seen, any ammonia, but use bichromate of potash to which is added one-fourth part of carbonate of soda. I have found, as the issue of many experiments, that ammonia is, in a great measure, the cause of reticulation in the film.

The exceeding simplicity of the above communicated pigment process will, I hope, have some effect in securing for carbon printing a wider application, if only supported by the makers of carbon tissue and carbon requisites.

SOME THINGS SEEN AND FELT.

BY I. B. WEBSTER.

"Loads" of dirt have been removed, and the effect is most gratifying. In the February number I gave a view of things as they then appeared, and knowing what medicine would effect a radical cure, I began by clearing out the cause. The root of the evil "walked out," having a pair of feet made for that purpose. A negative free from holes was a rare thing to see up to that time, and now a negative with holes is truly a rarity. The same bath solution is still in use, as is also the same camera, shields, &c. I wish I could exhibit the metamorphosis to photographers that persist in wallowing and slobbering through their work, slinging things about as a common labourer working on the street would do. I simply filtered my bath, wiped out my shields, and went to work according to my old and well-tried rule of "careful manipulations." Read my paper as it was published in the proceedings of the National Photographic Association at Philadelphia and Buffalo. I recommended certain ways for doing certain things, and I know that good results will follow always. For instance, during the past three years, I have trusted others to prepare glass, supposing they would keep up my "tried plan," but rusty glass became the rule. Why, I could not tell until this present experience, and now I see it all quite plain. The rule that works well is this. Make a strong solution of concentrated lye, immerse the glass in it one at a time (I treat varnished negatives and new glass alike); leave them in the solution until they are clean; then, with a rag, tuft of cotton, or patch, wipe them (rub hard) all over both sides, and then wash the lye all off with water, after which immerse them in a dish containing commercial sulphuric acid (strength unimportant), where they ought to remain at least one whole day; take them from the acid singly; let them drip well; wash in water, and pass them into water, where they will remain until you are ready to albumenize. Do not allow the glass to dry from the time it is first put into the lye until after it has received the substratum of albumen. This is an important point.

I am working up to this routine, and my supply of rusty glass is diminishing rapidly, and I fail to get a "map of the world" on my negatives. By giving a little attention to this every day, it will be but a short time until you will find a large supply of good plates on hand ready for use. I use the white of one egg to from ten to twenty ounces of water, and add a little iodide of potassium to clear it, and a few drops of ammonia to improve its keeping qualities. If the solution is too strong of egg, the film of the negative will come out rough. Filter with care before using, and be careful in setting the plate away to dry, in order to prevent foreign matter from coming in contact with the albumen surface while wet. Above all things have your hands free from silver, soda, cyanide, or other deleterious solutions, or it is sure to spoil all your plates. Use a rack to dry the plates, as that gives a chance for the solution to run off the corner, and besides, there is no fear of capillary attraction carrying some destructive element upon the surface. Of course you old readers will fail to see any good in this rehash, nor would I two months ago; but my late experience teaches me that even old ones can learn if they will. I write this for those who read, and ask them to think it over.

There is another point I wish to make in this communication which I found all out of joint again, and that is the manner of dipping the plate in the bath. If you will refer to the papers mentioned above, you will see that I recommended that the bath be so tipped as to bring the back of the plate up. It is recommended by some writers to fix the bath-dish on an axis, so that it will tip to and fro, which is all very well, but not necessary. The glass bath is

generally set in a wooden box, sufficiently broad at the bottom to make it safe to keep it standing upright. Nothing else is needed. Keep the bath-dish upright all the time, tipping it back just enough to allow the dipper holding the plate to be easily immersed, and then straightening it up again, in which position it should remain until the coating is accomplished. Then tip back, remove the plate, and straighten up again.—*Philadelphia Photographer.*

Correspondence

CARBON EVILS.

SIR,—While many of us have been shouting "*Vivat chromotype!*" few have recorded their experience of coloured chromotypes. Every photographer who has seen or heard of Lambert must remember what wonders were to be accomplished with albumen colours; although Lambert did not say they were permanent. I am one of his everyman-his-own-artist pupils, and have tried the colouring of chromotypes with some success. Enclosed you will find a carte painted in this way a year ago, and on looking at it you will at once say, "The colours, although pretty to look at, are good for nothing; they will soon fade." This should be known as widely as possible, both by photographers and the public.

I have before me a very neat circular, issued by a carbon man to his patrons. On one page he sings the praises of coloured chromotypes in the following terms:—"The colouring matter of these pictures is incorporated with the material of which they are composed, not on the surface, as is the case with ordinary coloured photographs; hence their beauty and durability. They are done all sizes, from carte upwards, and are made to resemble the finest burnt-in enamel, and have been pronounced by those best able to judge as absolutely permanent." This is all very prettily printed in gold-bronze after Marcus Ward's best style; but if it isn't true?—"There's the rub."—Yours truly,

JO. VESTRIS.

THE SILVER BATH.

SIR,—Having had some little experience for some years past with cyanide in the negative bath, perhaps I may be allowed to add a few words to the present discussion upon its effects. I have always been in the habit of mixing my bath in the old style. Distilled water, pure silver iodide of potassium, and nitric acid, *quantum suff*; before adding the iodide and silver, sunning; some time after adding a trace of carbonate of soda; I then filter and acidify. By these means I believe I obtain a bath of the most perfect possible purity, as every trace of organic matter in the water is precipitated under the action of light.

Some weeks ago I made up a new bath as usual, and worked it very hard for some time, when, without any warning, it fogged; the fog could be wiped off the film, leaving the image pure and bright by reflected light, but very streaky in the direction of the dip. A solution of about a quarter of an ounce of cyanide in an ounce of water was made, and sufficient added to cause a permanent precipitate; after filtering the bath gave excellent negatives without further addition. The other day a further supply of silver in crystals was added to strengthen it, after which it fogged again, but was once more cured by the same process. The bath is now neutral and very rapid. Upon both occasions fine needle-like crystals were deposited after filtering, which were again filtered out. I send one of my filter papers for your examination. Perhaps you will be kind enough to inform me what the precipitate consists of.

My experience of cyanide in the bath amounts to this—that it is in nine cases out of ten an immediate and effectual remedy for fogging, and leaves the bath pure and nearly neutral. I therefore advise all operators to give it a fair trial.—I am, sir, yours truly,
W.
Tuunton, April 18th, 1877.

[We have not time to make an analysis, and the amount of filtrate is too small for effective examination. It is, doubtless, chiefly cyanide of silver, and has that appearance.—ED.]

To Correspondents.

A. E. S.—The word *cliche* is a French word, and is commonly used in photography as an equivalent for a negative. In its wider signification, it means any plate that can be printed from. (2.) The nitrate of iron developer may be prepared in various ways; but the following is considered the best. Dissolve
Nitrate of baryta (powdered) ... 1 ounce
Water ... 8 ounces

In a separate vessel dissolve

Protosulph. of iron ... 1½ ounces
Water ... 8 "

Mix, and decant or filter, to remove the white precipitate, which is sulphate of baryta. 3. The exposure for nitrate of iron is about the same as for sulphate of iron development. 4. The filling up of fine lines in intensifying reproductions of fine engravings somewhat depends on the intensifier used. If a sulphide be used for development it will not fill up much. Some operators, in such cases, develop, fix, wash, and dry the image; then run round the plate an edging of varnish; wet again, apply a five-grain solution of bichloride of mercury until the image is of a uniform grey tint, wash, and apply a two-grain solution of iodide of potassium. 4. A wet plate from which all free nitrate of silver has been washed cannot be developed with an ordinary developer without the addition of nitrate of silver. It may be developed, however, by the alkaline method; but the collodion should possess a larger proportion of bromide than is generally used in ordinary collodion for wet work. 5. The distance the camera should be placed from an object to reduce it to a given scale depends upon the focus of the lens. If, say, you wish to take a copy of an object one-tenth of the original size with a lens of ten inches focus, it must be placed at a distance of nine feet two inches, which is ten times the focal length of the lens, and one focus added. Again, if you wish a reduction of twenty times with a lens of six inches, the distance would be one hundred and twenty-six inches, being twenty times the focal length and one focus more. 6. It is possible that you may obtain gun-cotton made at a high temperature, of some manufacturer, but it is not an article kept in trade, as a rule. We believe Mr. Rouch manufactures some. Hopkins and Williams also. We believe that Mr. Werge keeps pyroxyline. 7. We don't remember any substance of the nature of asphaltum which is white in colour. White shellac is perhaps the nearest. This will dissolve in alcohol, by the aid of gentle heat. 8. Glycerine is the best aid to keeping a moist plate for a few hours. 9. To make polished metal goods dull, so that they may be more easily photographed, make them very cold, and place in a room containing warm vapour. This vapour by condensing on the surface makes them dull. If a cup or other hollow vessel, may be made cool enough to condense the ordinary vapours of the atmosphere by placing a piece of ice in.

LUX.—We prefer the ridge form in preference to a sloping front light. But if you prefer the latter, the form indicated by diagram No. 1 in your letter, being simplest, will answer best.

A. Z.—The mixture of citric acid and nitrate of silver you mention is not intended for use as an intensifier alone. It is intended to be added to a solution of pyrogallio acid, or a solution of iron. Many photographers use it to add to their ordinary iron developer, and after developing, proceed, with a little fresh iron solution and the citro-silver solution, to intensify.

GALA.—Bronze powder will not in any way affect a carbon print, and the cards may therefore be used. There is one objection, however: if the carbon prints so mounted be placed in an album with silver prints the latter will assuredly suffer. 2. The best kind of negative for retouching is a clean thin negative, without any trace of fog. It should not be much intensified.

GREEN.—Yellow tannin may be obtained of most drapers.

S. S. (Jersey).—We should of the two prefer *Rues*. For a person not versed in dry plate operations, we should recommend the coffee process. That you mention is very excellent, but we should think difficult to manage for a beginner.

A. CLARKE.—There is no work on opal pictures that we know of. Jo. VESTRIS.—We fear that your drama "*The Sage of Surbiton*" will scarcely be suitable for publication in our pages; but it may be interesting to see the manuscript.

M. B. F.—For ordinary landscape work—that is, for taking views of natural scenery—a single landscape lens will answer every purpose. Portraits may be taken with such a lens, especially in the open air in a good light. It will not give portraits as sharp as a good portrait lens, but for large heads it will give sharpness enough.

Several Correspondents in our next.

The Photographic News, May 4, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

AN INSTANCE OF THE IMPORTANCE OF PHOTOGRAPHIC ILLUSTRATION—SCOTELLARI'S PROCESS IN VIENNA—A NEW TEST PAPER.

An Instance of the Importance of Photographic Illustration.—We have been favoured with an early inspection of a technical work, which proves in a most striking manner the value of photography for purposes of illustration. We allude to a treatise on Gunpowder Machinery, from the pen of Mr. J. C. Hay, C.E., the Inspector of Machinery to the War Office. As our readers are doubtless well aware, Great Britain provides much of the machinery for other countries; and not only in Europe, but in far-off China and Japan, British engineering has acquired a reputation which testifies amply to the skill and ingenuity of Englishmen. But machinery such as is set up now-a-days in our factories and workshops is rarely simple enough in its character to be easily understood; and when foreign purchasers receive their goods, much still remains to be done in putting the same together, and placing in working order. In many cases, no doubt, native engineers are forthcoming, to whom the working of the engines and plant might well be entrusted; but, in the first place, they must know how the machinery is to be set up, and its general aspect when at work. Again, there are would-be purchasers, who want to know something of the machinery, first of all, in which they are about to invest their money, and desire to learn its nature and character before acquiring it. It is to satisfy these classes that the treatise in question has been prepared. The book, as we have said, relates to the manufacture of gunpowder, and in it are to be found a series of a dozen or more photographic illustrations of the machinery employed in this class of work. One plate shows "the incorporating mill," where the ingredients are ground together; another, the "mixing machine," and so on. The photograph shows that it is a real machine here set up, and not an experimental structure. If but a drawing had been given, there would be no proof indeed that any machine of the kind described in the treatise had ever been constructed; and purchasers of machinery, it should be remembered, like to know that the firm from whom they receive their goods have had some experience in the manufacture. It is nothing new, as engineers will tell you, to show a drawing and describe a machine of the making of which a firm has as little knowledge as the purchaser himself. For this reason, therefore, photographic illustrations are peculiarly valuable in a work of this sort. Those who study the volume may rest assured that the author is experienced in the subject of which he treats, while at the same time the reader knows that the Birmingham firm, Messrs. Taylor and Challen, under whose auspices the book is published, and whose machines are here represented in working order, are thoroughly acquainted with the manufacture of the gunpowder machinery which the book describes. Another point, which beginners will at once appreciate in respect to these photographic illustrations, is this. Had the volume been illustrated by minute and detailed working drawings, which would have been necessary in order to secure the full confidence of would-be purchasers (if photographers had not appeared), these drawings could have been used by unscrupulous firms abroad and at home, in building up the machinery for themselves; so that after an engineering firm had lost much time and trouble in working out a series of machines, and constituted the manufacture of these a speciality, others would come in and enjoy the fruits of its labours, by having recourse to the drawings published. Now in the case of photographs the matter is very different. Although a camera picture conveys to the mind a wonderfully clear conception of the manner in which a machine

works, and is an invaluable supplement to a working drawing, it is of itself almost useless in the hands of a mechanic. The lens has given every bearing, every screw, and every wheel out of proportion, and to seek to work by scale, with the aid of a photograph only, would be a most disheartening job. Thus, as we desire our readers to understand, photography has been most aptly made use of in this instance, for both the advantages and shortcomings of the process have been made to tell in the application.

Scotellari's Process in Vienna.—M. Scotellari's proposition to employ violet glass in the studio has not been better received in Vienna than with us. Indeed, after the unfavourable report of the commission appointed by the French Photographic Society, we are not likely to hear much more of the subject. In Vienna, M. Fritz Luckhardt, the well-known portraitist, experimented in the matter, but his trials failed to confirm the statement of M. Scotellari. M. Luckhardt essayed the violet light in two ways. He exposed a plate in the camera, one-half of which was covered with violet glass. In this case the difference, if any, was against the employment of the tint. Next he exposed a negative to the light in a printing frame, covering it with alternate stripes of violet and transparent collodion varnish; in this case the print was a little paler where the violet varnish had covered it. M. Luckhardt essayed to obtain some of the violet varnish and curtains direct from M. Scotellari's agent, in order to make as impartial a trial as possible; but it is only to licencees, it appears, that these materials are sold. A circular of M. Scotellari states that the cost of adapting a studio in the manner recommended by that gentleman is about fifty francs, supposing the atelier does not measure more than ten square metres. It may be mentioned that in Vienna this is not the first experiment that has been made with studios of coloured glass. The court photographer, M. Angerer, whose works were better known a dozen years ago than they are now, built a magnificent studio with blue glass, which we had the pleasure of visiting soon after its erection. In the end, however, it was found to offer no advantage over studios glazed with ordinary glass. M. Luckhardt seems to think that the charming soft illumination emitted by violet light has led, more than anything else, to a belief in its more valuable properties.

A New Test Paper.—Litmus paper has so long retained its position among chemists as one of the best and most delicate tests for acids and alkalies, that it is not likely to be replaced. Moreover, the cost of preparing paper with litmus extract is so small that test papers can be produced at a very small cost indeed. However, some experiments, made by M. Frebault, and reported in the *Journal de Chimie et de Pharmacie*, deserve to be mentioned, as pointing out that litmus and turmeric are not the only substances that can be employed without trouble for test purposes. M. Frebault uses the picramates of potassium and sodium, which have a bright red colour, and turn greenish-yellow when treated with the weakest of acids. Filter paper soaked in a solution of picramate of calcium may also be used for testing for acid in the same way, and, according to M. Frebault, may advantageously replace litmus test paper.

COMPARATIVE EXPERIMENTS WITH DRY PLATES.

BY H. J. PALMER, M.A.*

A PROJECTED photographic jaunt among the peaks and passes of Switzerland in the course of the coming season, and the very laudable desire to bring home with me as perfect a batch of negatives as possible, have led me to experimentalise upon the different kinds of dry plates which were accessible to me, with a view to the final selection for work among the Alps of that process which

* Read before the Liverpool Amateur Photographic Association.

would seem best adapted to supply me with the perfection I aim at.

My experiments in this direction proved so interesting to myself, that I became impressed with the possibly erroneous notion that the detail of the results of my work might be of interest to others, and, indeed, useful, to some extent, as well. Accordingly, I determined to suggest them as a subject for discussion to-night, and without further apology will proceed to lay these results before you.

It will, of course, be clearly understood that in my remarks upon the various dry plates upon which I have been operating lately, I do not presume to say that this class of plate is necessarily faulty, and that necessarily good; I merely wish, as a dry-plate worker of some years' experience, to state how these plates have behaved in my hands, and to give a few accurate data which may, I think, prove useful to others in their work.

The following are the plates whose sensitiveness and general capabilities I have been testing in my late experiments:—Coffee, gelatine-bromide with water, gelatine-bromide with beer, Liverpool rapid, London, collodio-albumen, uranium, and Warnerke's tissue. I have endeavoured to expose these, as far as possible, under precisely the same conditions of light, upon the same subject, in the same camera, and with the same lens and diaphragm. The development has, of course, been varied to suit the requirements of each kind of plate. I have used the formulae prescribed by the several makers for their respective plates, and have in all respects endeavoured to deal fairly and impartially, and to obtain the best results to be had.

The subject I selected was Wallasey Church; the lens was Dallmeyer's medium-angle rectilinear, the stop that numbered four, and the light that of a misty sun, with the accompaniment, decidedly unfavourable to photography, of an east wind. The duration of exposure required by each plate was ascertained as accurately as possible by the plan of giving four exposures on a trial plate. Thus, for example, four slices of a uranium plate were exposed for five, ten, twenty, and thirty seconds respectively. The result proved that the portion of the plate exposed for ten seconds gave the greatest vigour under the developer, and this time was adopted accordingly. I have arranged some of the results in a tabular form, as follows:—

	Exposure	Development	Intensification	Result
Coffee	330 seconds	15 minutes	To any extent	Good
Gelatine-beer	30 seconds	7 minutes	Easy, but not required	Very good
Gelatine water	7 seconds	6 minutes	Difficult	Thin
Liverpool rapid	40 seconds	10 minutes	Easy	Very good
London	140 seconds	9 minutes	Easy	Fair
Pollitt	400 seconds	45 minutes	Easy	Very good
Uranium	7 seconds	13 minutes	Difficult	Fair
Warnerke's tissue	40 seconds	10 minutes		Good

The following, then, is the order of rapidity:—Uranium and gelatine-water (nearly the same, but slightly in favour of uranium, this plate showing signs of over-exposure), gelatine-beer, Liverpool, Warnerke's tissue, London, coffee, and, lastly, collodio-albumen.

The quickest to develop are the gelatine, the slowest the collodio-albumen, while the coffee plates preserve a safe

medium. Gelatine pellicle plates made with water are, as a rule, very disinclined to intensification by acid silver, but acquire a slightly augmented density when treated with chloride of copper and subsequent alkaline pyro. On the other hand, gelatine-water plates made from an emulsion in which bromide of ammonium is employed will intensify readily. Gelatine-beer, Liverpool, London, Pollitt, and coffee plates will acquire any amount of density with acidulated silver; but the uranium, in my hands, obstinately declined intensification. My classification in order of excellence is as follows:—1. Gelatine-beer. 2. Pollitt. 3. Coffee. 4. Liverpool. 5. Gelatine-water. 6. London. 7. Uranium.

The negatives themselves will enable those who please to do so to readjust the order of this classification. The gelatine-beer plates, in my (possibly unskilful) hands, have proved the only ones which produce anything like freedom from stains, spots, pinholes, stripes, &c., and, at the same time, may be depended upon with absolute certainty (provided they are guarded from damp), for a dense, brilliant, and printable negative. I have been unfortunate in my batches, both of London and uranium plates; for I failed to find a single plate in either package which was free from defect in the structure of the film. I have never tested the London plates before; but I have often obtained the most perfect results from the old uranium plates. I do not appreciate the dense films of the latter as they doubtless deserve. They put an end, it is true, to all change of blurring; but it seems to me that the advantage is gained at the expense of brilliancy.

The collodio-albumen and coffee plates give much the same character of picture, and that one of the greatest delicacy and beauty, combined with vigour and brilliancy. With regard to the former, however, although the resulting negatives are often perfection itself, there is the counterbalancing disadvantage of their exceedingly sluggishness under the developer. To an amateur with, necessarily, very limited time at his disposal, the undoubted truth of a new application of an old adage, "*Ars longa, vita brevis*," comes home with a painful force when he faces, as I have done, at the close of a photographic "out," many dozens of exposed collodio-albumen plates, and all to be developed at the rate of forty minutes per plate.

My coffee specimen needs some apology. I was in a great hurry to produce it, and had no time to apply a substratum; hence the defects which are evident upon the film. I am, however, much pleased with these plates. I had never produced a coffee plate before; but with the aid of an old number of the *British Journal*, I obtained a successful batch at my first attempt. As the image appeared under the developer, it was quite equal, with the exception of the pinholes, to the best of my gelatine friends. It was only on the slipping of the film, and in my efforts to save it from destruction, that the damage was done to the negative. The crop of pinholes manifest upon this and upon the collodio-albumen plates might, perhaps, have been avoided by the use of a new bath. In the collodio-emulsion plates I know not how to avoid them. But here comes in the manifest advantage of the gelatine process. There is absolute certainty, with a gelatine emulsion, that every plate in a batch will be precisely like to its fellows. This is not so with bath plates; nor is it the case with collodion emulsion. The bath may sicken of one or more of the many ills to which baths are liable in the very middle of the process of the preparation of a batch; and, as to emulsion, there is no doubt that evaporation produces a speedy difference in the consistency of the films, and therefore a difference in the character of the resulting negatives.

I have lately returned from a few days' camera work in Wales, and here I had an opportunity for testing plates of different kinds under the most unfavourable circumstances of light and weather. Liverpool plates gave me some beautiful results; but some of these split up into multi-

tedious fragments of film during drying. Gelatine also afforded me some excellent negatives, in spite of the most deplorably bad light. Blurring, however, set in to an unusual extent, and I shall never again venture to use these plates in the field without backing.

I am sorry that I have been unable to make or procure plates prepared by some of the other well-known processes. I hope, however, that what I have done, and what I have said with reference to the few specimens before us, may afford us a theme for an interesting and profitable discussion this evening.

PHOTOGRAPHIC POISONS AND THEIR ANTIDOTES.*

UNDER this heading it is proposed to treat merely of the more prominent symptoms upon the human system of such chemicals in the photographic laboratory which are most injurious and most commonly employed; the antidotes alluded to are also such as can be promptly made use of in case of poisoning by any of the above chemicals. It must always be borne in mind, however, that in order to verify the symptoms of a patient in a case of poisoning, the calling of a doctor should not be dispensed with for a moment. The more important antidotes are specified because a doctor is sometimes not to be obtained speedily enough, and because, too, the photographer may be called upon himself to give personal assistance. That both accidental and intentional cases of poisoning occur from time to time in the photographer's studio is only too well known, and the exercise of the greatest caution in regard to noxious chemicals does not, nor will it ever, cause a cessation of these lamentable occurrences.

Accidental poisoning occurs sometimes from technical, and sometimes from economical reasons; the most numerous cases are, however, wilful, and, of course, in these cases precautions are all but useless. Suicide by poisoning is, nevertheless, not so frequent as some people may imagine; in Austria, for instance, not more than thirty-three suicides come by their death by such means.

Sulphuric, Hydrochloric, and Nitric Acids.—Symptoms: Very acid taste, a vivid burning in throat and stomach, fearful stomach-ache, choking sensations, painful and acid sickness, the vomit containing blood and a chocolate-brown substance (or yellow in the case of nitric and hydrochloric acids), insatiable thirst, rising of the stomach, red, sanguineous, and white urine, small but quick pulse, cold hands and feet, great fear and restlessness.

Treatment: The patient should drink large quantities of water containing white of egg or soap; or water containing calcined magnesia, or, if this is not at hand, chalk, egg shells, or lye-water.

Chromic Acid and its Salts.—Symptoms: Great inflammation of the stomach and kidneys, the vomit of a bright yellow colour, while purging rapidly sets in.

Treatment: Magnesia or bicarbonate of soda in water. Oxhydrate of iron, as also solution of tartaric and citric acids, are recommended, as well as sugar, water mixed with some syrupy substance.

Oxalic Acid.—Symptoms: Acid taste, burning in throat and stomach, rapid vomiting of blood and darkly-coloured substances, rapid sinking of strength, slow beating of the heart, very weak pulse, cold blue colouring at the finger ends, cramplike convulsions.

Treatment: Administration of lime-water; or, if this is not at hand, of powdered chalk or egg-shells. Further, may be administered, black coffee, musk, and camphor.

Chlorine.—Symptoms: Very active attack upon the mucous membrane of the breathing and olfactory organs, difficulty in breathing, inflammation of wind-pipe and lungs.

Treatment: Breathing of spirit of wine vapour, smoking

a mild cigar, careful sniffing of ammonia or aniline, and drinking of sweetened liquids containing alcohol.

Iodine and Iodine Compounds.—Symptoms: Similar to those given by mineral acids in case of direct swallowing of iodine or tincture of the same; brownish-yellow vomit, and, in case starch is present in the stomach, this will be rendered of a bluish tint. The brown colour disappears in the presence of ammonia (different in this respect to nitric acid).

Treatment: Administration of starch, white of egg, paste, magnesia milk.

Bromine and Bromide Compounds.—Symptoms: The same as with iodine, but the starch contents of the stomach are not turned blue.

Treatment: As in the case of iodine.

Alkalies.—Symptoms: Burning in the neck, choking, vomit often containing blood, and always of an alkaline character, purging, and violent pains.

Treatment: Administration of very dilute mineral water, of tartaric or citric acids, or of vinegar or lemon juice, oil emulsions in dilute acids.

Ammonia.—Symptoms: Similar to those given by alkalies, great secretion of saliva and mucus, affection of the respiratory organs, occasionally convulsions and cramp.

Treatment: As in the case of alkalies.

Copper Compounds.—Symptoms: Persistent disagreeable taste of copper, vomit of a green or bluish colour, colic, purging (often bloody and then black), tenesmus, headache, giddiness, cold, touching sense impaired, lameness.

Treatment: Vomiting and purging continued and facilitated, without, however, administration of oils; afterwards administration of white of egg, mixture of nine parts of fine iron filings with four parts flowers of sulphur, magnesia milk (two parts calcined magnesia, twelve parts powdered sugar, ten parts water and, if desired, addition of orange syrup).

Mercury Compounds.—Poisoning by means of mercury, as is the case with other metals, may be acute and chronic. The latter, which is particularly to be guarded against in breathing mercurial vapour, should not now occur among photographers, since the practice of Daguerreotype is no longer popular. It is with cases of acute poisoning by means of bichloride of mercury (corrosive sublimate) that we have especially to do.

Symptoms: A disagreeable metallic taste, burning in the throat, swelling and discolouration (whitish-grey) of the tongue and throat, choking, vomiting of a white and often bloody substance, purging with blood, tenesmus, cessation of urine, small pulse, syncope, defect in the touching sense of the skin, and total sinking of energy.

Treatment: Administration of drinks containing plenty of white of egg, or, if this is not at hand, milk or paste. At intervals, but only with advantage at the beginning, may be administered freshly precipitated sulphide of iron, or a mixture of seven parts of the finest iron filings and four parts flowers of sulphur mixed, or not, with honey.

Silver Compounds.—Symptoms: Similar to those given by copper poisoning, but occasionally with more violent nervous symptoms, giddiness, convulsions, &c. The membrane of the mouth is coloured white or grey, the vomit is white, but turns gradually grey or black on exposure to air.

Treatment: Application of emetics, then white of egg, solution of common salt (not too much of the last) to form insoluble albuminate and chloride of silver.

Gold Compounds.—Symptoms: A little fever and black discolouration of the teeth; secretion of saliva, and in the case of a patient having taken large quantities, the symptoms are the same as when soluble silver compounds are swallowed.

Treatment: Administration of white of egg in drinks, tannic acid, magnesia, milk (see copper compounds).

Lead Compounds.—Metallic taste, burning pains in the stomach, vomit of milk-white substances, colic, sometimes

*Photographisches Jahrbuch.

with stoppage, but occasionally with purging and secretion of saliva; often violent pains in the legs, lameness, giddiness, material diminution in the pulse action.

Treatment: Administration of emetics and purgatives, and especially of the sulphate salts, such as sulphate of zinc, bitter salts, Glauber's salts, and, at a pinch, white of egg, milk, and liquids containing tannin.

Zinc Compounds.—Symptoms: Powerful metallic and acrid taste, white colouration and wrinkled appearance of mucous membrane of the mouth, violent sickness, giddiness, coldness of the skin, convulsions.

Treatment: Administration of drinks containing white of egg, and of decoctions of tannin substances; also of alkaline carbonates and milk of magnesia.

Carbonic Acid.—Symptoms: Headache, giddiness, choking at the chest, diminution of muscular energy, loss of senses, languor, sinking of the pulse and respiratory organs, general paralysis.

Treatment: Plenty of fresh air, cold bath, warm foot-baths, and same treatment as in poisoning with carbonic oxide.

Carbonic Oxide and Coal Gas.—Symptoms: The same as those in the case of carbonic acid, and particularly giddiness, ringing in the ears, headache, fainting, loss of senses, paralysis, convulsions, sickness.

Treatment: Admission of fresh air to the system, blowing of the same into the lungs, artificial respiration, cold douches, vinegar clysters, friction of the hands upwards, smelling of ammonia, administration of strong coffee.

Cyanogen Compounds.—Symptoms: Cramp-like, laborious, and intermittent respiration, weakness, diminution of heart beats, loss of senses, absence of control over one's actions, convulsions, starting out of the eye-balls, which are immovable, dilation of the pupils, smell of prussic acid in the breath, at times secretion of saliva and foam in the mouth.

Treatment: Rapid clearing out of the stomach with stomach pump (emetics work too slowly as a rule); chlorine water, solution of one part of chloride of lime in forty-five parts of water with a few drops of hydrochloric acid; dilute ammonia in gum is usually without action, as well as mixtures and solutions of sulphate of iron and soda, or precipitated sulphide of iron and magnesia. To revive the nervous system, applications of cold water to the head and spine, while the patient is in a warm bed; artificial respiration; alcohol is also recommended.

Alcohol, Ether, and Chloroform Vapours.—Symptoms: These fall into three not very readily divided periods of various duration—namely, irritation, sinking, and paralysis. First of all, unsettlement of ideas, swimming of the eyes, vivid fancy images, broken talk, dreams, outbursts of rage, convulsions, sickness, then sleep, loss of senses, languor, general insensitiveness, dilation of the pupils of the eye, weak and slow pulse, peculiar respiration, but yet in deep breaths, diminution of bodily heat, and finally cessation of action of the heart and breathing, cold, clammy perspiration and syncope.

Treatment: Sprinkling with cold water, rubbing, introduction of fresh air into the lungs, artificial respiration, electric treatment, administration of seltzer water and plenty of cold water.

THE STEREOSCOPE.

We are indebted to the late Sir Charles Wheatstone for a series of investigations on binocular vision, which finally culminated in the invention of that now very popular little apparatus, the stereoscope. It was in 1823 that Wheatstone called attention to a fact until then hardly noticed, namely, that the perception of relief in objects is the result of the superposition of the images, one on each eye; but the images slightly differ from each other. The mind, guided by the experience of many years, receives in this way the impression of various distances; and Wheatstone discovered that this impression may also be given to the mind by two

pictures, if each is drawn so as to correspond, respectively, to the image received by each eye. In order to prove this, Wheatstone invented the stereoscope. Considered from the standpoint of pure science (apart from its practical application for amusement, instruction, and research, and the binocular microscopes and telescopes that have grown out of it), this discovery of Wheatstone's is, perhaps, as interesting as any other invention of recent date, not excepting the kaleidoscope, the telephone, the pseudoscope, and the revolving mirror for measuring the velocity of light, &c. Sir David Brewster, who was erroneously supposed by many to have invented the stereoscope, used often, while insisting on the importance of this new conquest in physical science, to describe this instrument unhesitatingly as the most remarkable gift with which the study of binocular vision had been enriched.

The first stereoscope by which Wheatstone demonstrated his discovery was a reflecting stereoscope. Two vertical mirrors were placed so as to make, respectively, an angle of 45° with the axes of the eyes, and in such a position as to reflect the rays coming from the right and left into the eyes, the mirrors being joined at a middle point between the axes. Two perspective drawings, correctly made, so as to correspond with the image which the real object would make in each eye, were then so placed, at the right and left, as to cause these images in the mirrors to coincide in the act of vision, and the illusion was perfect. Wheatstone found later that he could dispense with the mirrors and simplify the apparatus by using two prisms, to which he had lenses attached so as to magnify the drawings. Brewster finally had prismatic lenses made, joined by their thinnest edges, by which small drawings, placed at the distance of, say, three inches, could be made to coincide for the vision. It should, however, be mentioned that Duboscq, of Paris, was the first to give to the stereoscope the simple practical form in which it is now seen in the trade; but its popularity did not become established until photography came to its aid, to make binocular pictures perfect in all their details.

It was at the first universal exposition in London, in 1851, that Duboscq exhibited a stereoscope, and then, for the first time, the instrument became noticed by the public although it had been known to scientists for thirteen years during which time Dr. Carpenter and others had continually, in lectures on physical sciences, exhibited the instrument and demonstrated the principles of Wheatstone's discovery. According to the statements of one manufacturer of optical instruments, a long time elapsed before the people began to appreciate the beauties of the stereoscope; and for several years no sales of any importance could be made. But at last its merits were realized, and suddenly a large demand sprang up. The stereoscope soon became in fashion, and the manufacture of the different forms of the instrument (varying in price from 50 cents to 100 dollars), the grinding of the prismatic lenses, and the production of the photographic pictures on paper and on glass, have now become an important branch of business, in which thousands of artists and workmen are occupied.

A recent application of the stereoscope, especially useful for the student of science, consists in the reproduction of drawings of geometrical figures, illustrating the various forms used in the study of stereometry, such as the projection of solids in descriptive geometry and spherical trigonometry, and especially in crystallography. In the latter science, it may be made especially useful, as, in this way, not only the crystals themselves, but also the forms resulting from the interpenetration of two crystals, may be explained better than can be done in any other way. The relation of various systems of crystallization, the transition of one form into another, the relation of the nucleus to exterior forms, the directions of cleavage, the position of axes of crystallization, the laws of double refraction, and various other more or less intricate subjects, may thus be made simple to the average understanding; and these studies may awaken some interest in this important subject, and simplify it to those who cannot afford to buy the

expensive and bulky models of crystals. A number of stereoscopic pictures may thus be made equivalent to a collection of models costing as many dollars as the pictures cost cents.—*Scientific American*.

HOW TO PRINT IN CARBON.*

BY C. GENAILE.

I suppose you have the materials on hand, and your negative ready. Take a piece of the tissue, about two feet, and steep it in a solution of bichromate of potassium, one ounce to forty of pure water; make up three ounces of bichromate and one hundred and twenty of water, which can be used three or four times; put it into a tin dish, or anything; roll your tissue backwards and forwards in it until you get it to lay smooth; leave it in two minutes, and pull it out over the dish, and hang it up to dry; while in this wet state it is not sensitive to light, and can be done in daylight. I prepare it in the evening a little before dark. Be careful to have no dust or bad odors about where you dry and keep your tissue. It takes several hours to dry, and cannot be dried by the fire; the room must have dry atmosphere in it. When dry, or nearly so, it is very sensitive, and must be kept in the dark or yellow light in a tin box. It is most sensitive when the weather is a little damp.

The negative that you print from must always have yellow or black paper around the edge, so that the light does not touch the edge of the tissue printed on. As you see nothing on the tissue when printed, you use the photometer with the little numbers on it, and put a small slip of silvered paper according to the instructions you have received, and print to between three and four visible; make a few trials and develop, and you will soon find out the right time. It varies according to the strength of the negative, and the state of dryness of the tissue, which is one of the most important things to study so as to regulate your time. It requires patience to learn.

When printed, put your tissue in cold water, but first prepare a porcelain plate of polished glass the size, or a little larger than your tissue print; rub some of the wax solution on the plate, then coat it with plain collodion, which, when set, immerse in cold water till the water runs smoothly over the plate; then take your tissue print which is in the water and lay it on your collodionised plate which has water on it, so that you can more easily move your print into its right place; put it on a flat table or board, lay your rubber cloth on, and pass the squeegee over it gently, which drives off the water and any air-bubbles; leave it for ten or twelve minutes under a flat-iron, or any weight, with a piece of blotting paper under, then put it in a dish of pretty warm water, and when you see it commence to turn black all around the edges, which it does in five or six minutes, or often much less, you can take hold of the paper by one corner, and very gently turn it back; do not let it slide, but lift carefully, which paper you throw away. The tissue is then on your white porcelain, and if you gently throw warm water with one hand on it, the picture will develop by itself beautifully and gradually till it is fully out; if too light, you will know you must print it more, or, if too dark, less. When properly developed, pour a concentrated solution of alum over it to harden it, then wash for a minute under a tap of clean, cold water, and put it in your rack to dry. When dry, touch out any spots with lead pencil, looking through by transmitted light at the time of working on it, so as to get the right tint; then cut out a piece of transfer paper the size of your print, put it in a solution of warm water, and lay the slippery side on your carbon tissue; put the rubber cloth on and squeegee as you did the first time to drive off bubbles and water. Leave it to dry, then pull it off; you cut and mount the same as the other prints, and burnish; practice, and have patience till you succeed, and you will be happy. Read carefully Lambert's

* *Practical Photographer*.

instructions after you have worked at it, and you will understand them better then. You cannot use too much care, cleanliness, and patience.

NEGATIVE ENLARGEMENTS,

WITHOUT PIGMENT DIAPOSITIVES, BY MEANS OF COLLODION AND THE SCIOPTICON.

BY VON KOLKOW.

It is very well known that diapositives prepared by means of collodion are always hard, and lately there are pigment positives which are very highly recommended. I myself give the latter a preference, on account of their easy preparation for the production of enlarged negatives, because they are very fine and transparent. But to him who has no good, clear, and very fine prepared pigment paper, or who is not a proficient in the pigment process, in order to prepare a suitable and rightly exposed pigment picture for enlargement, I recommend very much a collodion positive, with his common portrait collodion thinned with two-thirds of an equal mixture of alcohol and ether. These diapositives, when developed, look very faint, but show all the details, and are very fine and transparent, like pigment pictures. On cloudy winter days, when it is very difficult for photographers to execute large plate directly on account of long exposures, it is very easy to make a carte-de-visite. This varnished negative, which should not be too much strengthened, but nearly over-exposed and presenting full details, must be copied by means of the sciopticon, in order to receive a diapositive of it.

In a dark room, or towards evening, I put the sciopticon on a suitable long board (a), remove the objective and the slide of the same, and fasten in front of the condensing lens (b), the negative (collodion side in front), and opposite the common camera (c), the objective of which must be of equal height with the condensing lens of the sciopticon, diaphragm down two-thirds, and make an equally large diapositive (behind the condensing lens, the back-glass of the lantern must be replaced by a fine ground-glass, not white opaque-glass); the right exposure is soon found, generally in from fifteen to twenty seconds. This diapositive is to be fixed, and, without varnishing it, to be fastened again in place of the negative in front of the sciopticon; after that again prepare, in the camera, negatives of all required sizes. Plates of fifty by sixty centimetres I prepare in one to three minutes, according to the size of stop used in the objective.

These negatives may, as you choose, be strengthened, fixed, and afterwards retouched in the common way. They are just as fine as taken from pigment positives, and give excellent copies on albumen paper, which can hardly be distinguished from those of directly taken large negatives. For taking the positives and the enlargements, the developer ought to be very weak; in order to get a fine precipitate, the common developer must be diluted with one or two parts of water. For the positive we have to look out that the same will be rich in details and transparent, and this can only be done with the sciopticon, which is indispensable; we have always the same light to work equally, and produce better enlarged negatives than by daylight; for negatives, which must be equally sharp in all parts, I take the landscape lens of a stereoscope double objective, or an Orthoscope Voigtlander No. 1. For half-length pictures the portrait objective is sufficient.

In no case do I reject the fine and beautiful pigment diapositives; but I desire to show those who are not acquainted with the pigment process how to produce just as good and fine negatives in this season, and also in the evening, by means of the sciopticon and collodion positive.—*Photographic Times*.

TUITION IN CARBON PRINTING.

BELIEVING that carbon printing will eventually become universal, and that every portrait photographer must ere long be able to meet the demand from the public, who will assuredly require permanent prints as knowledge on the subject becomes popularized, we look with great interest on all projects for efficiently teaching the process. And although, as technical journalists, we aim to give all the information possible in relation to the art we represent, we feel no jealousy of any other efficient means of imparting information. In fact, we may say frankly that whilst facility in carbon printing may be "picked up" solely by aid of the information which has appeared in our columns, and considerable experiment, it may be more readily and completely acquired by aid of tuition by a competent teacher, and we are heartily glad that facilities for obtaining lessons are increasing.

One of the primary qualifications in a teacher is personal skill. A man should himself be able to produce good work before he can teach another how to produce good work. It is possible, indeed, for a comparatively unskilled man to teach, and, by "teaching others, learn, himself, to spell!" But it is natural that the intending pupil should look for some credentials of the fitness of his tutor. And in the absence of an authoritative diploma the evidences of practical skill in the shape of good work, afford the best ground of confidence in the fitness and capacity of the instructor. We have pleasure in calling attention to the project of giving lessons to photographers generally of another gentleman of the highest ability, not only as a carbon worker, but as a portraitist generally. Mr. E. Greaves, of Halifax, is known by his work to many photographers. At the Photographic Exhibition held in London nearly two years ago Mr. Greaves exhibited a frame of portraits which were regarded by capable artists as the gems of the exhibition. They were in a bad position, near the floor, but were not overlooked by those who sought out neglected excellence. These were sufficient guarantee of the ability of the portraitist. Of the carbon printer we can speak, from examination of his work, in the highest terms. Every one of his prints we have seen are of the highest quality. It will be seen, moreover, from his announcement, that Mr. Greaves has a special system and special appliances for managing his printing with the greatest certainty, rapidity, and economy. And we have pleasure in commending attention to his project.

It also affords us satisfaction to call attention to the latest arrangements of the Autotype Company, as announced in our business pages. Arrangements for systematic tuition are established at Ealing, and lessons are available to non-licenceses and licenceses alike. We feel

satisfied that no course is so well fitted to secure new licenceses, as affording them demonstration of the simplicity, certainty, and generally satisfactory character of carbon printing. There is another item in the recent announcement of the Company to which we have especial pleasure in calling attention. One of the arguments which have been used by the opponents of patents has been the assertion that the existence of a patent is repressive of improvement, inasmuch as, it is alleged, experimentalists have little inducement to attempt improvements when they know that all that may be done in this direction will be absorbed by the patentees, who will gain the advantage, instead of the result being reaped by the experimentalist, or the community at large. The announcement to which we refer completely cuts away the ground for an argument like this in the present instance. The Autotype Company have been most praiseworthily liberal in their general arrangements, and in the announcement we have mentioned they perform a special act of grace. They announce that to all photographers who have been working their processes, and thus practically helping to solve the difficulties which beset the early paths of permanent photography, the Company will grant an Autotype licence on payment of the costs of stamp and registration. This is wise and well: and it will, we doubt not, have a beneficial influence on the general progress of permanent printing.

THE ELECTRIC LIGHT IN THE STUDIO AGAIN.

AS many of our readers know very well, the electric light has already received application by the photographer, who has endeavoured, by its aid, to make himself independent of the sun. The Woodbury Photo-Relief Printing Company, M. Disderi, and M.M. Goupil, of Paris, have, in turn, all employed the electric spark to aid them in their work; but have found, one after another, that this mode of illumination is at present hardly suited to their purpose. It is expensive to produce and to maintain, and, furthermore, its capacity is exceedingly limited compared to bright sunlight.

During the past twelvemonth, rapid strides have been made in the matter of electric illumination in Paris, the Gramol machine, a powerful magneto-electric apparatus, being used to generate the light. The *Chemins de Fer du Nord* station in Paris, and some large factories at Lyons, have been lighted up with electricity by the assistance of this machine, and so promising have been recent experiments that a much wider application of this method of lighting is spoken of. As our Paris Correspondent, M. Lacan, has pointed out, there is now more hope than ever of a universal employment of electricity for industrial purposes, since a simple mode has been devised of generating the light. According to our correspondent, M. Denayrouse is in possession of an easy and certain method of supplying electric illumination, which will revolutionise all existent apparatus. A constant and never-failing source of light is provided, and in such a manner as to present little difficulty to its use in everyday life.

So far as we can understand, M. Denayrouse employs for the purpose a compressed cake of earth, or rather kaolin, a substance well known to photographers. Running through the centre of this compressed mass is a material (we are not told what) which has a high conducting power, and which, at the same time, emits heat to such an enormous extent as to raise the surrounding kaolin to a high temperature. The cake of kaolin, indeed, becomes a bright and glowing mass, and in this condition is, in its turn, a conductor of electricity. So that after the preparation of the kaolin cake, it suffices only to pass an electric current through the centre, and maintain this current, in order to secure a constant light of exceeding brightness.

Should this method turn out to be really feasible, the problem of electric illumination will have been solved, and there is no reason why the idea of the inventor should not

be carried out, which is to have lamps of this nature in our streets, which would thus be lighted with electricity. There would be little trouble, doubtless, in distributing electric currents in all directions, and we should have a far brighter illumination than the rows of feeble yellow gas jets now afford. The lamps might be placed at a greater height, and in this way their influence would be felt at a greater distance.

Already this new source of electricity has attracted the attention of photographers, and Mr. Vander Weyde, we hear, is in treaty with the inventor respecting it. No doubt an easy and inexpensive method of lighting the studio with electricity would readily be taken up by photographers, for not only would it render them independent of the sun in winter time, but it would enable them also to take portraits in the evening as well as in the morning. And this, in the case of ladies who desire to be depicted in their dinner or evening dresses, is a matter of no little importance. Photographers, for instance, who could secure portraits of ladies, calling at the studio, on their way to a dinner-party or the opera, would not lack customers; and it is very probable that the electric light, suitably applied, may be made use of in this and other directions.

BICHROMATE OF POTASSIUM.

Blood Poisoned by Absorption of its Solution through the Pores.

BY J. D. COLTON.

Now that the subject of carbon printing is being so fully discussed, it may be interesting to those engaged, or about to engage, in the work, to read some experiences in poisoning with bichromate of potassium taken into the system through the pores of the skin by immersing the hands in its solution. It has not only been my misfortune to have suffered the greatest agony for weeks together, barely escaping death, but I have had the opportunity of carefully noting all the effects of such poisoning upon others as well as my own constitution. Such extreme cases are, I grant, of but seldom occurrence; but as all systems are liable to the action of the poison to some extent, the subject is well worthy of attention. The effects of the poison when swallowed are quite different from those of which I am writing, and as there is an abundance of information upon the former subject in print, I will confine myself to the blood poisoning simply.

The first symptoms of local poisoning are heat, itching, and tingling upon the ends and middle joints of the fingers, which, when examined, are found to be covered with small irregular red patches, upon which are numerous small elevations clustered together. In the course of a day or so these enlarge to the size of small beads, and are filled with a limpid fluid. In a short time these clusters run into each other, forming large blisters, which dry and crack, causing the most acute pain and itching. At this stage pustules begin to form all over the body, mainly down the spine, on the neck, left side, arms, and ankles, accompanied with considerable constitutional affliction, such as sickness, headache, thirst, fever, sleeplessness, and loss of appetite and senses. In my own case, after the third day I became nearly blind, the whole mucous membrane became inflamed, running and pain in the ears and throat. One case came to my notice in which the patient was covered with large patches which had all the appearance of having been eaten in with strong acid. This patient lost his appetite completely, and suffered much pain in the intestines and bladder. He lost consciousness every few hours, and had to be continually watched and aroused. When apparently insensible, he was so dejected in spirits that he endeavoured several times to commit suicide.

The effect of this poisoning upon scrofulous and syphilitic persons, when it does affect them, assumes a very troublesome and dangerous form, though strange it is

these persons are not so susceptible as healthy ones. The treatment—perhaps owing to the seldom occurrence—does not appear to be well understood. I sought advice from many able physicians abroad, but there seemed to be no reliable remedy but to allow nature to take her course, aiding the cure by paying strict attention to diet and habits. The following treatment I have found very successful in every case:—

Abstain from drinking beer, spirits, or coffee, and eat no potatoes, brown meat, salt fish, or sugar. Take plenty of exercise and fresh air. Avoid tobacco.

Take one teaspoonful liquor potassæ in a teacupful of barley water three times daily, before meals, for five or six days, after which take three times daily—

Tinctura serpentaria...	...	1 fluid drachm
Tinctura opii...	...	5 minims

The parts ulcerated and inflamed must be bathed frequently for several days, with

Liquoris plumbi subacetatis diluti... quant. suff.

The above treatment is continued until the sickness and pain have subsided, and the patches have lost the fluid they contained, and begin to heal; the hand, arms, &c., are then bound with unguentum resinos, and the following is taken for about ten or twelve days:—

Ferri et ammon. citr.	...	2 fluid drachms
Ammonium bromide	...	1 ounce
Potassium iodide	...	2 fluid drachms
Mist. camphora	...	12 ounces

Take one ounce twice daily, and following pills, two each night:

Extr. cannab. ind.	...	½ grain each
To make twenty-four pills.		

In my own case I found the free use of fresh butter advantageous, but as I have never tried it in other cases I cannot recommend it.

It is generally believed that by washing the hands in ammonia after sensitising, or using bichromate in any way, it prevents the poison from entering the system, by neutralising the acid; but this is quite a mistake, and a solution of bichromate rendered perfectly alkaline with ammonia poisons quicker, if anything, than an acid or neutral solution.

In conclusion, I trust I have not occupied so much valuable space to no purpose. This is a matter of the greatest importance to carbon workers, and this being the first mention I have seen made of so serious a drawback to the use of bichromate, I hope my remarks may elicit further information from those who have had experience in this direction.

THE CARBON PROCESS OF TO-DAY.

BY W. E. BATHO.

THAT there is a growing interest in the carbon process is patent to all who observe the signs of the times. That the interest will bring about the general adoption of this method of printing to the exclusion of "silver" is not certain; let those who like cry, "Carbon shall be king!" Any disinterested party can plainly see each system has advantages peculiarly its own. Certainly a skilful silver printer can do things no carbon printer can approach, notwithstanding all boasting. It has been well and truly observed, that were the same care and skill bestowed upon silver printing that is given to carbon, many of the complaints made against the former would be shown unjust. But the world loves change: the favourite of yesterday, to-day is led to the guillotine. A certain photographer once wrote:—

"When smiling fortune sheds her golden ray,
All crowd around to flatter and obey;
But when she hides behind a cloudy sky,
Our friends, our flatterers, and our lovers fly."

Let us write the epitaph on silver printing: "Henceforth our works shall be permanent," and posterity will possibly

utilise them for purposes foreign to our intentions. Well, well may they enjoy such Vandalism; it will not

"— vex thee, lying underground."

But to the story, to the story.

The pigmented tissues, as issued to the profession, all are more more or less familiar with. The carbon process only exists because of the permanency it promises. Clearly this must depend upon two things: first, the endurance of the gelatine, rendered insoluble by the agency of light; and, secondly, upon the permanence of the pigment imprisoned in such gelatinous film. That the latter has given some persons reason to doubt the lasting qualities is instanced by the letters appearing at times in the pages devoted to the furtherance of our art. Yet the clearest evidence on this point would only indicate an error in the selection of a pigment, and not a defect inherent in the process. But any proof given that the insoluble film holding the pigment is liable to any change, ending in dissolution with what may be termed ordinary wear and tear, would at once stamp the process as one brought under our notice with false representations.

The sensitizing of the tissue involves so many considerations that will account for some of the vagaries unjustly attributed to the manufacture of the material, that a little attention may not be time mispent.

If a piece of tissue be plunged beneath the surface of water contained in a tall glass vessel (simply to facilitate observation), the familiar appearance of a solution of greater density mixing with a lesser one will be seen to take place when the compound gelatine film is in contact with the water. The same phenomenon will also take place if bichromate solution be substituted for the water. Some of the sugar in the tissue is dissolved out, and hence a sensitizing bath must rapidly become contaminated with organic matter, to the injury of tissue subsequently sensitized therein. A reaction, having some similarity, takes place when the oxalate of iron, used in Mr. Willis's platinum process, is either made or exposed in daylight—that is, a decomposition of the sensitizing agent is brought about before exposure takes place—in the carbon process, a want of purity in the whites is the result; in the platinum-type, stains all over the surface of the paper are produced. Another circumstance, having a close connection with the sensitizing of tissue, must be noticed—that is, the variety in gelatine, as shown by the difference in the quantity of water different samples absorb in the cold. It needs but little exercise of the reasoning powers to perceive that of two samples of tissue, alike in every respect save one, and that a difference in absorption, such would, were it sensitized in the same bath, show a corresponding dissimilarity in sensibility; and practice proves the reasoning correct. Such discrepancy can also be brought about in a much simpler way, and one far more likely to plague the practical photographer. If tissue under different hygrometric conditions be immersed in the sensitizing bath, and kept therein until the usual sign of sufficient immersion is obtained (*viz.*, the tissue becomes flat), that sample which previously contained the most moisture (other conditions being alike) will have the least proportion of bichromate therein, and, hence, occasion diminished sensitiveness. Having seen tissue sensitized when "bone dry," and, again, in such a state as to be decidedly tacky, this last observation seems to me not an unnecessary one.

To sum up. In producing uniformity in the tissue, so far as sensibility is concerned, first an uniform quality of gelatine is required, which may be left to the manufacturer; second, a constant degree of moisture in the tissue; third, fresh solution each time of sensitizing; fourth, if the squeegee be used to remove part of the sensitizing bath from the prepared sheets, in order to facilitate drying, a regular and constant pressure must be used. Some of these precautions may be thought too precise;

each, however, is welcome to his opinion. No doubt there are individuals who succeed, no matter if they work with a saturated bichromate bath, or one having .0001 per cent. I am not so fortunate, but I must follow the tissue to the finished print.

(To be continued.)

PHOTO-COLLOTYPE PRINTING.

BY M. T. H. VOIGT.*

WITH the bichromated albumen of Obernetter it is advantageous to employ a first film less thick. To arrive at this result, there is poured upon the plate a sufficient quantity of the solution, and this is dried on a stove at a temperature of 15° to 20° R. If you proceed to a higher temperature, the film easily lifts; therefore, it is necessary to follow exactly the instructions here laid down. For the same reason the plates must not be withdrawn from the stove until they are quite dry. Very often tiny fissures are produced in the first film, but these are of little importance. Once dry, the plates are placed upon black velvet, and exposed to light from the back. During the summer the exposure should last from fifteen to twenty minutes, or in less intense light thirty minutes or even more are necessary, while in the winter an hour or an hour and a half is required. Before applying the second film, the plates are plunged into water warmed to 40° to 45° R. Herein they are left for some minutes, until the film has softened. During their sojourn in the water the surface is rubbed with the end of the finger, so as to remove any dust that may have become attached.

The softened film is rinsed in warm water, and then the second film is formed by pouring upon the middle of the plate the mixture given below, the same being permitted to run successively toward each angle, to chase away the water upon the plate. This second film is dried by means of a stove heated to 40° R.

Second film.

1st.—Gelatine	90 grammes
Water	720 "
2nd.—Isinglass	50 "
Water	480 "
3rd.—Bichromate of potash	15 "
Bichromate of ammonia	15 "
Water	300 "

A new simplification has been imported into photo-collotype printing by the use of soluble glass (alkaline silicate), which avoids the isolation of the first film, and its washing in warm water. The mixture for the first film is prepared by beating albumen into froth, and adding soluble glass and water; you beat again and filter through linen. Here are the proportions:—

Albumen	25 grammes
Water	45 "
Silicate of soda...	6 "

The solution is poured upon the plate like collodion, and allowed to dry spontaneously. This done, you wash in a bath of water, rinse, and finally dry, after which you can at once proceed to the application of the second film.

Another way of employing the alkaline silicate as a first film consists in pouring a solution of soluble glass upon a plate, and allowing it to dry; afterwards the silicate is rendered insoluble by plunging it for a minute or two in a solution of nitrate of baryta. The plate is withdrawn, washed carefully with pure water, and then the application of the second film is proceeded with, which is composed of:—

Gelatine	5 grammes
Isinglass	3 "
Bichromate of ammonia	2 "
Water	70 "

To avoid air-bubbles, the mixture must be poured with

* Continued from page 202.

considerable care, and extended with foresight upon the film of soluble glass. A large wet brush or a bit of blotting-paper will aid materially in the operation.

The majority of the fissures that are to be seen upon the plates are due to impurities in the substances employed, and especially to the isinglass and gelatine. As the former contains particles of grease difficult of removal, it may be dispensed with, and all inconvenience avoided by employing only purified gelatine. This latter is rendered pure by being cut up into small fragments and put into cold water, the water being frequently renewed, until a solution of oxalate of ammonia (one part of salt in twenty-five of water) produces no precipitate in the washings.

A few drops of ammonia are then added to the white of an egg, and the latter beaten to a froth. You continue to beat, adding the gelatine which has been dissolved by a mild heat, the white of one egg sufficing for 2-50 grammes of gelatine. Then two or three drops of acetic acid are added. With a glass rod the liquid is stirred until it is thoroughly mixed, and it is then boiled and filtered. The viscid mass is allowed to stand, during the night, in a dialyser, in water, so as to remove every trace of acid. Finally, the gelatine is dried, in the open air, at a temperature of from 15° to 18° R.

As a supplement to the processes which I have just described, I will detail the *modus operandi* modified by myself, as also the particulars of a drying box of my own invention, both of which are to be recommended by reason of their simple nature.

I employ a film of pure soluble silica, which will only keep good a day or two. A very slight thickness suffices to produce the adherence of the second film with the plate. To secure this, I pass over the surface slowly and uniformly—so as to prevent the formation of any air-bubbles—a broad and soft camel's hair pencil impregnated with soluble silica. This is applied to the glass plate after it has been ground, and the film is allowed to dry. By operating in this manner the white of one egg will suffice for a large number of plates.

I do not wash the plates in water before the following treatment:—I place upon a table a zinc vessel, and give the same a perfectly horizontal position by means of a screw tripod and a water level. The gelatine destined to furnish the second film must neither contain sulphur nor acid, gelatine of this sort being friable and easy to remove from the plate during printing. Neither must it be partly soluble in cold water, because it then furnishes inferior impressions.

When choice has been made of a good gelatine, it is necessary to employ the undermentioned method of purification:—140 or 150 grammes of gelatine are put into 1200 grammes of water; the latter is changed several times during an interval of several hours, having care to replace the quantity that is removed. This treatment having continued for some time, the gelatine is dissolved by mildly heating it; the white of an egg, beaten to a froth, is added, and the whole is well beaten up to mix it. The vessel is then put upon a sharp fire, and brought rapidly to the boiling point, having a care to stir it up continually to prevent the gelatine sticking to the bottom of the vessel.

As soon as the liquid begins to boil, it is allowed to cool, and is then filtered through a flannel. Although somewhat grey to begin with, the liquid soon becomes clear and transparent.

To filter the gelatine I make use of an apparatus which permits me to preserve an even temperature during the whole course of the operation. I have a vessel of tin in the form of a funnel, between the walls of which is introduced some warm water by means of an opening therein. A funnel is put inside, and the filtering operation goes on. The liquid is thus surrounded on all sides with warm water. The apparatus is set in action, and you have merely to place underneath suitable vessels to receive the filtered liquid.

In the next place I prepare the following solution:

Bichromate of potash...	20 grammes
Bichromate of ammonia...	10 "
Water ...	300 "

This is mixed with the gelatine, which is now ready for the second film. I pour upon a plate placed in a perfectly horizontal position a sufficient quantity of this mixture, and spread it by means of a piece of filter paper. If there is any tendency to escape at the side the latter must be rubbed with the finger. The superfluous liquid is then permitted to escape into the vessel to be employed later, and the plate is put into the drying-box. In order to operate always under the same conditions, and avoid irregularities in the surface, it is well, especially in winter, to maintain an even temperature in the laboratory—say that of 18° Reaumur, for example—and to arrange matters so that while it is employed the gelatine is maintained at a temperature of 35° R., for otherwise it will thicken, and then it is impossible to spread it evenly.

In order to keep the gelatine warm, use should be made of a rather deep saucepan in which is placed an iron support capable of carrying the vessel containing the bichromated gelatine. Enough water is put into the saucepan to reach the bottom of the gelatine vessel. At the level of the water is placed a bent thermometer, which enables one to read off the temperature outside the saucepan. The last is then covered, placed over a petroleum lamp, or a gas jet, and I heat until the thermometer indicates 35° to 40° R.

The upper portion of the gelatine is often filled, after filtration, with a quantity of air-bubbles occupying a thickness of several centimetres. Here is one cause of inequality in the film, and for this reason it is well to make use of a vessel for the gelatine which has a tube at the lower part (like the spout of a coffee-pot). In this way the lower layer of gelatine in the vessel only is employed, which is exempt from air-bubbles.

(To be continued.)

PHOTOGRAPHY IN THE TROPICS.

BY M. PAUL LEVY*

THE difficulties which beset the inexperienced photographer in the tropics are pretty well known. The chemicals behave in a totally different manner to what they do in Europe, and their reactions and results are by no means uniform. During my voyage to Nicaragua, I have gathered some experiences, some of which were acquired previously in Mexico and upon the African coast, and these I find to be in accordance with the views of M. Ramon de Espinola, a chemist and photographer of Granada.

Here they are in the form of notes:

Do not carry out with you any utensils of gutta-percha; they melt. For the sensitizing bath, whether vertical or horizontal, it is preferable to employ a vessel of glass covered with straw or rushes, and placed in a special box of wood. For other baths it is best to have papier-maché varnished. For if gutta-percha is to be rejected, it is also well to have as little glass as possible, because of the risk of transit across the country.

Again, there should be few glued articles among your apparatus; this should be screwed or dove-tailed together. In a warm climate the humidity and moisture separate all glued surfaces.

Have everything exceptionally stout and solid, so as to resist sudden shocks. Have the feet of instruments furnished with a framework or bag of stout canvas, to be suspended underneath the apparatus full of stones, so as to steady it in a gale of wind. If a dark-tent or closet form part of the apparatus, it must be borne in mind not to place the same in full sunlight, as it is then impossible to work therein; nevertheless, by making the covering very

* Communicated to the French Geographical Society.

thick, a double thickness of black inside, with a cover of shining white, a serviceable tent may be secured. On the African coast, I had a structure made of dense foliage, under which I erected a tent of ordinary construction.

It must be remembered that a ray of light penetrating the dark room does far more mischief here than under ordinary circumstances.

You must never operate between the hours of eleven and two. The pictures obtained during this interval are detestable; the rays of light are too vertical, and the whites too glaring.

As few objects as possible should be of iron, because of their extreme liability to rust; everything should be of copper, brass, or galvanized iron.

Doublet lenses for portraits or lenses should be rejected. You should have a simple lens for landscapes, or another separate one for portraits or groups, if thought necessary. In photography applied to topography, or large work, it must be borne in mind that a lens giving straight lines must be employed.

Very small diaphragms must be used even when the exposure has to be prolonged; there is always too much light, not enough repose, lack of sharpness in the outlines, and absence of detail.

The waxed paper process gives good results, and may be conveniently employed with the portable dark slide of Marion; but the exposure—already a long one in Europe—required is more lengthy still here, where very small diaphragms must be employed.

The dry collodion process has given me but very so-so results in the tropics. This may be by reason of inexperience on my part. It must be remembered that neither glass nor diamonds to cut it are to be had under most circumstances.

As regards the collodion, I would remind the reader that the heat has a very energetic action upon the ether. After many trials I at last decided the following *modus operandi* to be best. I received my collodion from Europe with the iodiser separate. I employed the bromide and iodide of cadmium, the iodide of ammonium, and that of potassium. As the solution is always of a capricious nature, according to the state of the atmosphere, the electric tension, pressure, temperature, &c., I divide it into a series of numbered bottles, into which I put the bromide and iodide alternately in excess, so as to be able to employ the one or the other as I may desire. In this way I can control, to a certain extent, the time of pose according as I have a portrait or landscape to take. I have two graduated vessels, or collodion pourers, into which, at the moment of collodionising a plate, I introduce a sufficient quantity of normal collodion, and mix with it a suitable dose of the iodiser; I stir with a glass rod, allow the liquid to stand for a moment, and then coat my plate.

You must not prepare your own pyroxilin in the tropics; let it come to you from Europe, and send your order a long time in advance, for such goods are very slow in transit. Do not send your albumenized paper with chemicals, nor liquids with solids. It is well to divide one's packages into small parcels or boxes, so as to be carried by mules, the boxes being long rather than high or wide, and not more than one hundred pounds each, twice this amount being the burden of one mule. Everything should be in duplicate.

For the sensitizing bath employ recrystallized nitrate of silver as pure as possible; for sensitizing paper, the ordinary nitrate will do.

Always cover up your baths when in use. From the tiny moths who come flying around your light, to the bats who have the weakness of misbehaving themselves in the presence of acetic acid, there are many things to injure your solutions.

Glass rods should invariably be employed when possible. The fingers emit too much perspiration to be used with impunity. If you perspire much from the forehead, wear a

turban, for a drop of perspiration falling upon a plate or into the bath must injure them.

Develop with iron, and intensify with pyrogallie acid; fix with hyposulphate of soda, and have nothing to do with cyanide.

The clichés should be carefully varnished, and very promptly, for the films are very liable to split. The ferro-prussiate paper of Marion may be frequently employed, and is economical. Waxed albumenized paper is soon destroyed. Paper should be received frequently in small canisters surrounded by chloride of calcium.

As to distilled water, that is a grave question. There is none to be had. The photographer should carry a small still for making his dipping bath, at any rate. Rain-water is in general use, which is saved for the dry season; it is treated with nitrate of silver to precipitate any salts in suspension, and is then filtered. But the result is always unsatisfactory, for, take whatever precautions you may, the water always contains some organic matter and noxious gas, which have an injurious influence.

COPYING NEGATIVES.

BY H. M. BRILES.*

AT various times and in various journals have been published very full descriptions of how to obtain first-class enlargements from negatives already in the hands of the artist. For this the fraternity ought to be very thankful. It is not, however, with the process of first obtaining a glass positive, and then from that a negative, that I am now to deal, but with such cases as cannot by any means come under such a process. Having within the last three years made thousands of enlargements, and having had, in nearly every case, to work from some old picture—frequently one much faded, sometimes all covered with scratches, but oftener dim and dirty—I have found that a great deal of ingenuity, much skill, and great care are required to produce, from such a picture, a pleasing enlargement; nor will I say that it can always be done, since frequently the artist has but the faintest shadow of a picture to work from.

Of course, a suitable lens, copying-box, cones of various lengths, and copying board are required. Use any good quarter-tube supplied with central stops. A small stop will be needed in copying groups and large heads. Place your board in good strong light (I prefer sunlight—direct, if it can be had, without even glass between); sensitize a plate the size of the negative desired, and remember that in this operation an old red, but good, structureless collodion is by far the best. Fix the picture to the board, focus, and expose plate precisely as you would for a life picture, except that you will find it more convenient to copy the picture head-down, as you can focus more easily, and, I apprehend, more accurately. The matter of exposure is the vital one in copying. An over-exposure will flatten the copy, and so spoil it; an under-exposure will be at the expense of detail. The shortest exposure which will faithfully render the detail will be the best. In life-work redevelopment or intensification should be the exception; but in copying it is imperatively required in nine cases out of ten; and it certainly requires good judgment to decide when the operation is complete.

After development, wash well, and strengthen with pyro. and silver. If you fail to obtain sufficient intensity, wash well and fix; then wash again, and again apply the pyro. If you had not sufficiently washed your plate after fixing, you will have ugly-looking markings. Do not be alarmed, however. Wash well again, and now flow the plate with a solution of bichloride of mercury (corrosive sublimate), when the markings will begin at once to grow fainter, and the process of intensification will go rapidly on. With the bichloride solution you may carry on the intensification, if desired, until the plate becomes white again, and

* Practical Photographer.

then, if still weak, you may wash well and flow with a solution of water to which a little water am. has been added, when the plate will again become black and several degrees more intense. Retouch your negative as carefully as possible, ever bearing in mind that if a thing is worth well doing, now is the time.

Bad backgrounds may be blocked out very easily as follows:—Paste any waste piece of old silvered paper or other non-actinic paper over as much of the background as possible, and not in contact with the figure; then with a brush and some of Gihon's opaque, work up to the margin; with a steady hand and perseverance you will succeed finally. To print in a weak background, and give strength, solidity, and smoothness, lay the print on a clean glass, and then lay both into the printing frame, and with Gihon's opaque cover the image carefully to the edges and all over its surface, leaving the portions to be printed in clear glass; the thickness of the glass will then, between the opaque and the image, print in the shade, and this will prevent any sharp lines. If you do your work well, you can scarcely fail of success.

PHOTO MAGIC LANTERN SLIDES.

At a meeting of the Photographic Section of the American Institute, during a discussion on the above subject, Mr. Roche said that, for lantern slides, emulsion plates gave the finest films, good bath plates next, and carbon last; that silver pictures for transparencies gave brilliancy and more contrast, and that many of the pictures exhibited were under-exposed and over-developed, thus giving too great a contrast, and lacking in detail. Pictures for the lantern should be full of detail, soft, and brilliant. Anything approaching a veil or fog over the picture is fatal. The high lights should be almost clear glass. The opinions of the other members coincided with the remarks by Mr. Roche.

Mr. Newton, the President, remarked that he presumed it was not generally known, even by emulsion workers, what an increase of sensitiveness to the action of light was produced on an emulsion plate by the application of the alkaline development. In this respect it differed entirely from the action of an acid iron developer on an ordinary bath plate: whereas the iron developer on an ordinary plate nearly destroys its sensitiveness to the action of light, the effect of an alkaline developer of an emulsion plate increases its sensitiveness at least a hundredfold. He also stated that he had fogged an emulsion plate during development with the light of a kerosene lamp turned low and protected with manilla wrapping paper. This was occasioned by simply holding it a little too near the light to determine the stage of development. The fog commenced nearest the light, and diminished in the ratio of its distance from it. In the centre of the plate, beneath the rubber of the pneumatic holder by which it was held, and where it was entirely protected from the action of light on the back, it was wholly free from fog, and remained perfectly clear. By exercising more care, in removing the lamp to a greater distance and protecting it with more thickness of paper, he met with no further difficulty. He gave it as his opinion that much of the trouble experienced by those trying emulsions arose from developing in too strong a light.

Mr. Roche stated that, in working some good emulsion, the plate during development fogged. He therefore stopped out all light possible in the dark room, and then the plates developed clean and perfectly free from fog, confirming the remarks of the President on that subject.—*Scientific American*

Proceedings of Societies.

GLASGOW PHOTOGRAPHIC ASSOCIATION.

The meeting of this Association held on Thursday, the 19th inst., at the Andersonian University, Mr. JOHN STUART, President, in the chair, was a "popular" one for members and friends.

Dr. JOHN NICOL gave a descriptive lecture on Aberdeen and its

surroundings, the pictures being by Messrs. G. W. Wilson and Co. The series was a large one, and every picture was a subject possessing interest. The lanterns were supplied and managed by Messrs. Mason and Co., and the light was clear and steady.

After votes of thanks to the Lecturer and to the Chairman the meeting was adjourned.

At a meeting of the recently appointed Carbon Committee, the Secretary was instructed to send the following letter to the Bristol Amateur Photographic Association:—

Mr. H. A. H. DANIEL, Hon. Sec.

DEAR SIR,—Had your Association resolved that application for renewal of Swan's patent in connection with carbon should not be opposed by them, that would have been simple, and no one could have had the least objection; but the reasons you have given, and which form part of the resolution, were in no way warranted, and are open to objection.

You misunderstand our object in thinking we desire to disturb any one's true interests, much less that they should make sacrifices; but we wish to see to the public good. We do not object to the patent running its full course, and those interested getting the full benefit from fourteen years' rights or monopoly; our object is to try to prevent undue extension.

You say that "under existing patents good and reliable tissue is manufactured." We have no need to answer this further than to say that there are, and have been, many complaints by the users respecting the quality and irregularities of the tissues.

"Non-renewal would chiefly affect professional photographers, and would not increase the scope for fresh discoveries." We think it would affect all equally in proportion to their interests and their practices of the art, except that amateurs do not pay so much for their licences; and if it be amateurs who make all the discoveries it will certainly hamper them, because they cannot do anything which may not be questioned.

"It is generally admitted as incontrovertible that few, if any, discoveries of importance have emanated from the professional community." If this proposition be incontrovertible, of course there can be no answer to it, but we do not believe this can be applied to the photographic any more than to any other profession. We believe that industry, brains, and genius overcome what are called insuperable difficulties.

The steam-engine was not discovered by a professional, neither was steam navigation or railway locomotion. Sir William Thomson is not a professional electrician; Arkwright was not a professional spinner; Dr. Livingstone was not a professional missionary; Daguerre was not a professional photographer, nor Fox Talbot, nor Archer, nor Swan, nor Johnson, and we suppose that even Lambert cannot claim that designation; yet were they not all really professionals? We think they were, and claim that they have all been as much professionals as any others who can be thus designated.

Our Committee have given instructions that this answer should be forwarded to your Association, to which we, at the same time, desire to show all respect, and to present our good wishes.—I remain, dear sir, your respectfully,

ALFRED ROBERTSON, Hon. Sec.

Glasgow, April 19, 1877.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

The monthly meeting of this Association was held on Thursday evening, the 26th ult., at the Free Library, William Brown Street, the Rev. H. J. PALMER, president, in the chair.

The minutes of the previous meeting were read and passed, and Mr. W. E. Potter elected a member of the Association.

Mr. H. HOULGRAVE exhibited some negatives taken by Bolton's washed emulsion, on plates one and two years old, showing no deterioration; also a gelatine plate prepared by King's formula.

The SECRETARY said he had written to Mr. L. Warnerke, who had kindly sent him some specimens of his tissue negatives. These he would pass round, and they would see what excellent results Mr. Warnerke was able to secure with his tissue. One or two, they would see, were of greater softness. These were on a new kind of tissue, which would shortly be in the market, and which was quite transparent without any application of collodion, as was previously necessary. One of the negatives had all the appearance of having been taken from the landscape direct; but it was merely a negative obtained by printing by superposition from a positive print obtained at a shop, and exposed to gas-light for a minute, the long exposure overcoming the difference of texture in the paper print. Mr. Warnerke said he rarely now heard of failures in development, but if such happened it was invariably due to bad chemicals. Sometimes failures occurred in the inability to remove the film from the supporting paper. The cause was either that the tissue was not dried first, or that rubbing the back of the negative with turpentine had been omitted. Some failures were caused by not thoroughly fixing the

negative, and this could be avoided by fixing in the light, as the mistake could be then seen at once. If the negative showed a want of brilliancy, the remedy was to begin the development by using at first a very small quantity of pyrogallie acid, and increasing it when necessary.

A hearty vote of thanks was passed to Mr. Warnerke for his kindness in allowing the members the pleasure of inspecting his excellent negatives.

Mr. J. A. FORREST then introduced to the meeting Mr. J. Valentine, of Dundee, who met with a most hearty reception. He (Mr. Forrest) handed round a series of pictures taken by Mr. Valentine for the use of artists, Mr. Valentine giving an interesting description of his method of working and producing them.

A letter was read from the Glasgow Photographic Association in reference to the question of carbon patents. It was considered, however, that the Association could not take any action in the matter.

The PRESIDENT then read a paper, "Comparative Experiments with various Dry Plates (see page 205). The paper was illustrated with a number of negatives and prints taken by the various processes.

A vote of thanks was passed to the President for his paper, and some discussion followed.

Mr. FORREST, in reference to the long development of collodio-albumen plates, recommended that a number of plates should be placed to soak in the pyrogallie developer for some time; they could then be more rapidly developed, using one dish for the silver in which to finish the plates singly.

It was decided to have an excursion to Shrewsbury, Haughmond Abbey, &c., on Wednesday, the 16th instant.

The meeting was shortly afterwards adjourned.

Talk in the Studio.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.—The next meeting of this Society will take place on Tuesday, May 8th, at 6A, Pall Mall, East (the Summer Exhibition of the Society of Painters in Water Colours being on view), when the discussion on the "Nitrate Silver Bath," introduced by Mr. John Spiller, F.C.S., will be resumed. Also a paper will be read by Captain Abney, R.E., F.R.S.

ALLEGED MAGNETO-PHOTOGRAPHY.—Mr. William Brooks has recently communicated to the South London Photographic Society some astonishing statements (which we find in both the *Photographic News* and the *British Journal*) regarding impressions which he claims to have obtained in a sensitive plate exposed, in total darkness, to the influence of a magnet—said impressions being analogous to those due to light. The probabilities are that the investigator has overlooked conditions in his experiments which would give another and more likely cause for his results; and certainly no one will accept the latter according to his interpretation, in the absence of proof of the most convincing and conclusive nature. Mr. Brooks places a horseshoe magnet, about eight inches in length, poles uppermost, in a dark box. Over the poles, and about three-eighths of an inch distant, he suspends a card, blackened with Indian ink on both sides, and pierced with certain letters and geometrical figures. One-eighth inch above the card he places his sensitized plate, so that the latter is thus half an inch distant from the magnet. The exposure lasts from three to fifteen minutes, after which the plate is removed and developed. Where the perforated parts of the card have not intercepted the magnetic *aura*, or influence, or mode of motion, or vibration (the reader may choose his own terms), sometimes a negative and sometimes a positive image is developed, as if ordinary daylight had had access to the plate. It will doubtless astonish many to find that a card is capable of intercepting magnetism, as it is currently believed that that natural force acts through all interposed bodies—as would-be inventors of magnetic cut-offs have discovered to their confusion. But this is not ordinary magnetism—it is *aura*—the imponderable agent which Reichenbach conceived, and supposed to emanate from most substances, and to affect people as well as sensitive plates. Mr. Brooks wisely offers no opinion on the matter; but not content with the remarkable statements already made, he adds that upon his plate appeared a portion of a word, which was not in perforated letters on his card screen. After examining

the latter with great care, he discovered that the word was printed on the card, but was illegible except when the card was held at an angle, and then only very faintly, being thickly covered with Indian ink. This spoils a good story by making it too strong. If the card intercepted the magnetic *aura* so that the same could only act through the perforations in the first case, how could the same influence, acting on another part of the card at the same time, go through that card where the printed letters were impressed? And why did it not reproduce all the printing on the card instead of selecting a portion of a word? There is a mysterious discrepancy about it all, which makes us think that Mr. Brooks is a "medium."—*Scientific American*.

To Correspondents.

F. M. Y.—So far as our experience and observation go, any process of intensification which secures opacity by piling up material on the image is unsuited for reproduction of fine line work. We prefer methods which secure opacity by colour rather than by thickness of deposit. A brilliant intense image as possible should be obtained by the first development; then allow the plate to dry; next run an edging of varnish round to prevent the film lifting; moisten and apply a five-grain solution of bichloride of mercury, until a uniform grey tint is produced; wash, and then apply a one-grain solution of iodide of potassium until a greenish drab tint is produced, which is very adiacetic. Or a weak solution of old, used, hypo fixing solution may be employed instead of the iodide, and this will give a black image. The advantage of drying first is that the film and image are in a less spongy condition, and, therefore, the intensifying is less apt to spread and clog the fine lines. The use of a sulphide for intensifying is also good as securing density by colour rather than thickness. But you must remember that in making a reduced copy of a subject in line there comes a practical limit to the possibility of keeping fine lines clear and open.

B. L. G.—It is quite possible to make a toning bath which may be used at once. We frequently do so. We generally keep chloride of gold in alcoholic solution; making it by breaking a fifteen-grain tube into a two-ounce bottle, adding to the gold salt fifteen drachms of alcohol. To make a toning bath for working at once, we take a drachm of the gold solution, and mix it with a little prepared chalk into the consistency of cream. To this we add five or six ounces of hot water, at about 160° Fah. As soon as the solution is cool, it is fit to use, and generally tones satisfactorily. The sulphocyanide of gold toning bath is also ready as soon as it is made. 2. Quick washing in many changes of water is better than long soaking.

R. D.—As a rule, pyroxyline which gives a large undissolved residue on placing in ether and alcohol is bad, and is always inconvenient and wasteful.

G. G.—Registration at Stationers' Hall does not confer copyright: it is merely a record of existing copyright, which is necessary before an action for infringement can take place.

ENQUIRER.—Your question as to "what salts of potassium are used for enlarging" is too vague and indefinite for a satisfactory answer. Salts of platinum are not used for enlarging purposes. They are used in various toning and printing operations; but it depends upon what method you are working as to which salts are used. It is probable that you are thinking of Willis's process, which is patented, and can only be used by permission of the patentee. You will find all details in the specification, and should you wish to work the process, you will be able to obtain the materials of the patentee, or his agents, the Albion Albumenizing Company.

K. T.—It is better to use hydrochloric acid than salt, as a solution of the latter will hold a little chloride of silver in solution. If too much water is used it is difficult to get the chloride to deposit. Add a little nitric acid, and give it time. 2. Add the hypo negative fixing bath to the print fixing bath, and throw the silver as a sulphide with liver of sulphur; or, as a metal, with clean pieces of zinc. 3. The intensifying solutions may be added to the hypo solutions. 4. We cannot, as a rule, say what prices should be. But we may say unhesitatingly that we do not think 1s. 6d. each for 12 by 10 prints, including taking five negatives, and taking journeys, was too much, or indeed sufficient. Where journeys are undertaken to produce negatives, it is wise, as a rule, to make a specific charge for this, and then charge a legitimate price for the prints.

DAVE.—A negative after fixing, washing, and drying, may be intensified in various ways. You will find one method with mercury and iodide described above, or the method above described may be followed by hydro-sulphate of ammonia.

G. M.—Full details of the Exhibition of the Photographic Society will appear in due time. None are definitely fixed yet. Several Correspondents in our next.

The Photographic News, May 11, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

PHOTOGRAPHERS EN GRAND SEIGNEUR.—M. REMELE'S SECOND VISIT TO AFRICA.—HONOURS FROM ABROAD TO MR. FOX TALBOT.—AN ALCOHOL BATH IN CARBON PRINTING.—HARDENED PLASTER OF PARIS.

Photographers en Grand Seigneur.—Photography has long been a favourite pastime among the nobility and gentry of this country, while in Germany, France, and Russia the art has also been taken up by the highest in the land. More than one German prince is an accomplished photographer, and counts, both Russian and French, are known to fame through their work with the camera. In this country we have but to mention the name of the Duke of Edinburgh to indicate the rank of photographic amateurs, his brother, the Duke of Connaught, being also, we believe, both chemist and photographer. It is, in fact, due in no small measure to the amateur photographers of Great Britain that dry plate photography has reached such a high state of perfection in this country, dry plate workers, almost to a man, being amateurs. One British amateur has recently been at some great expense to carry on his cherished pursuit. Mr. Thomas Brassey, M.P., who has during the past winter been making a journey round the world in a yacht of his own, made it a pleasure to have a portion of the hold fitted up as a photographic dark room and laboratory, in order to secure pictures of the many interesting places he visited. Mrs. Brassey is an accomplished photographer, and has been for some years a member of the Photographic Society, and she it was, in all probability, who suggested this arrangement. The yacht is said to be a magnificent craft, built at Birkenhead, and named *Sunbeam*. Mr. and Mrs. Brassey were accompanied by several friends, so that the journey was made as pleasant as possible; and the size and equipment of the vessel were such as no doubt to render the life of its passengers very agreeable. The yacht first visited Buenos Ayres, then touched at various islands in the Pacific Ocean, paid a visit to Japan, China, and the East Indies, and finally came back home through the Suez Canal. There was consequently plenty of food for the camera, and, no doubt, Mr. Brassey has brought home a numerous and valuable collection of pictures. A tour of the same nature was made about a score of years ago by Prince Jerome Bonaparte, who adopted the same means for securing photographic reminiscences of his voyage. In this case, also, the yacht was a magnificent affair, carried a number of visitors, and was provided with everything to make matters pleasant. Whether the ship was run up a swamp creek on the West Coast of Africa, where nothing but rank grass and alligators abounded; or put into some cannibal port in the Pacific, where the warlike attitude of the savages rendered a lengthy stay impolitic, the Prince and his friends no sooner stepped from the inhospitable shore again into his own cabin, than they found themselves in an elegant saloon surrounded by all the luxuries and comforts of civilized life. Travelling and photographing under such circumstances are to be envied; the voyage must be pleasant while it lasts, and the photographs secured remind one still of the pleasures after these have passed away.

M. Remele's Second Visit to Africa.—While on the subject of photographing *en voyage*, we may mention that Herr Remele has again acceded to a request from the Emperor of Germany to accompany an expedition to North Africa as photographer. Our readers remember, no doubt, the graphic account given by M. Remele of his travels through the Libyan Desert, which appeared in these columns, and in which a photographer's troubles in the Desert are vividly depicted. M. Remele goes this time to Morocco, with an expedition of which Captain Zembusch, of the German Marine, has been nominated chief. The expedition goes with a message from the Emperor of Germany to the Sultan

of Morocco, and it affords, therefore, a peculiarly favourable opportunity for studying the nature and inhabitants of a country of which Europeans know very little. We are glad to hear that M. Remele has written to Dr. Vogel promising an early account of his travels, and this we shall not fail to put before our readers as soon as it appears.

Honour from Abroad to Fox Talbot.—We are glad to see that foreign nations do not omit to do honour to "the still living discoverer of the camera negative and paper print process," as Fox Talbot is described by a German contemporary. As negatives produced in the camera and prints upon paper include the whole practice of photography at the present day, acknowledgment of Fox Talbot's services is particularly wide and comprehensive. Our English pioneer certainly deserves all the credit given to him, for he, undoubtedly, invented photography as we now practise it, by indicating a means of securing transparent photographs from which prints could be taken. An influential industrial Society at Berlin, the Verein für Gewerbefleiß, has spontaneously elected Mr. Fox Talbot a honorary member, the honour being enhanced by the fact that many gentlemen of importance—among others the well-known chemist, Professor Hofmann—spoke in favour of the step with much warmth. The influence of photography upon science and culture formed the subject of the learned Professor's remarks, which were received with considerable enthusiasm. The proposition emanated from Professor Vogel, a name with which every one of our readers must be familiar.

An Alcohol Bath in Carbon Printing.—Some experiments made in the laboratory of the Industrial College of Berlin point in favour of the use of an alcohol bath after the tissue has been sensitized. If tissue is dipped into a bichromate bath, and then permitted to become partially dry by hanging for half an hour, and then further soaked for five minutes in a bath of spirits of wine, the drying afterwards goes on much more rapidly. In fact, by this plan of operating it is possible to get the tissue ready for printing within an hour, for as soon as it comes out of the alcohol bath it dries almost immediately. This tissue, sensitized at ten o'clock in the morning, is converted into finished pictures by the single transfer process by four o'clock the same afternoon. However, as we explained in these columns a few weeks ago, the method adopted by Mr. Mayland is a simpler one still, while at the same time the tissue dries quite as expeditiously as when alcohol is used, Mr. Mayland's plan being to keep the wet tissue in a warm cupboard to facilitate the driving off of moisture. Alcohol is likely to have an influence upon the bichromate salt, but, at any rate, the employment of a spirit bath is an expensive and roundabout arrangement.

Hardened Plaster of Paris.—M. Caussin, a German chemist, has discovered a method of hardening plaster of Paris, and rendering it in every respect as resistant as stone or metal. It is a fluid which is had recourse to, and which, impregnating the porous compound, renders this at once of a granite-like nature. Any fine details or lines upon the plaster of Paris are preserved in all their delicacy and sharpness, so that for photo-reliefs the process will be especially useful. There is little difficulty, as photographers know, in securing a gelatine image, or its impress in plaster, but these are, as a rule, too delicate for hard wear and tear. Let us hope that the process of hardening plaster of Paris discovered by M. Caussin is a sound and practical one, and easily applied. Unfortunately, the inventor has so far kept the nature of the fluid he employs a close secret, and has not yet been prevailed upon to divulge its nature.

PHOTOGRAPHIC DIFFICULTIES.*

BY F. YORK.

THE subject I have selected is one, I fear, that will not be considered of that instructive nature it ought to be. I

* Read before the South London Photographic Society.

will endeavour to combine a little mirth with a few practical hints. Many of the incidents I shall allude to caused me much annoyance, vexation, and trouble. I can now smile at them, although they had a very contrary effect at the time. Taking views of London is very trying to one's nervous system. I used to be considered rather amiable. I am thought the opposite now, and all through this class of work. The English climate is so variable, and the London atmosphere so peculiar, depending upon the wind. Living as I do at the extreme West, I have scores of times left home when beautifully bright, and the wind from the West; journeying eastward the atmosphere gradually gets misty, but at three miles distance the buildings at the ends of very short streets are very hazy. I have lingered about for hours whistling, like a sailor does, for a breeze, with the same result, I imagine. I return home without unpacking my things. When the wind is from the East, I have often seen the sun almost red with haze, and concluded it was useless leaving home, and, to my annoyance. I have found that the day in the city has been unusually fine.

I never attempt a view unless the light is favourable, for the slightest haze is fatal to a London photograph. There are some views, particularly distant ones on the Thames, that require exceptionable days. I have gone to two places in particular as many as twenty times in the season without taking a satisfactory negative: it is a common thing to go to many places three or four times, and do no good, owing to the atmosphere. These peculiarities are so common that I am obliged to regulate the work accordingly, going eastward when the wind is from the East, and keeping westward when the wind is from the West, these being the two prevailing winds. I have often risen at three o'clock in the morning to do early views, and have been anxiously watching the rising of the sun, waiting until he is sufficiently high; but my old enemy is rising with him. In this case nothing can be done, for the general fire-lighting has begun, and London is in a mist until ten o'clock. I have found it almost an invariable rule that work done between seven o'clock and ten is unsatisfactory.

When I first attempted street work, I tried a tent. Many are the troubles and vexations I have encountered. The first form of tent I used was an imitation Smart's, with flat top on which was placed the water-tank. It must have closely resembled a shower bath, for I have often been surrounded with a crowd, and described when inside as a cove taking a shower bath. The next form I used was Leake's box tent, this was a very convenient form, but as it was so constantly knocked and blown over, I was obliged to discard it. I then tried Wilson's. The one great advantage with this was its extreme portability; but there were many disadvantages—dust, wind, the curiosity of outsiders to lift it up to see what was going on inside, and the difficulty of finding places to erect it. The tent nuisance at last became so unbearable, that I resolved to start a trap, and purchased a two-wheeler of Mr. Earl, of Worcester. This was a mistake, for it could not be used with the horse in the shafts, and it is very difficult to find retired spots where the horse could be taken out; this circumstance was the cause of many mishaps. I was once engaged on Whit Monday, the horse standing near the shafts with his nose-bag on, when a pleasure van with a band playing most vociferously startled the horse, the nose-bag became entangled with the end of the shaft, the plunging of the horse upset the cart just as I had stepped out of it, and you can readily imagine the mess caused by the upsetting of eighty ounces of bath, and the majority of bottles smashed. Had I been inside, I think my most intimate friend would have failed to recognize me half-an-hour afterwards smothered with silver bath, colloidion, &c. This, of course, terminated my day's work. It would not have made a bad subject for an illustration in *Punch*. Several other accidents happened. When in use, legs were used to make it firm; on two or three occasions my assistant attempted

to get inside before they were adjusted, when suddenly down went the cart, and extinguished him. The next vehicle I had built specially for me; the style is a hooded wagonette which answers admirably; I have not had any mishaps with it. It is often an object of great attraction, and many guesses are made as to its use: these are some of them—an ambulance, fever or small-pox carriage, and when near a cemetery, the workhouse hearse (the horse being black tended to corroborate this idea).

I am now so well known to the police that I get great assistance from them in keeping back the crowd. When I find a difficulty in taking a photograph from the pavement I get into the gutter; the traffic keeps them back from the front of the camera. I am sometimes so bothered that, after focussing, I take the bearings and turn the camera at right angles and talk to the crowd, asking them to be steady just while I count one, two, three, up to fifteen; my assistant puts the plate in, turns round the camera, and exposes, whilst I am telling them that if they will only be quite still, they will have the pleasure of seeing their faces for sale in the *shop windows*, with the ballet girls and bishops. In resorting to this dodge it is necessary to use a larger plate than necessary, to allow for any error in turning round the camera. The following is a common and most annoying circumstance: imagine a view to be taken across the street in a very busy thoroughfare with only occasional sunshine. You see in a few minutes the sun will be obscured; you rush to expose, when an omnibus stops to take up or put down a passenger; when started the sun becomes obscured; after waiting for five minutes or more the sun is bright, a loitering cabman catches sight of you, and asks your charge to do a good-looking fellow like himself. It is useless to remonstrate. The next obstruction is a mud cart, then a stream of heavy traffic carts loaded with straw, or a block—all this time the sun is shining beautifully. When all this is cleared off, cloudy again, and no chance of taking the photograph. This is not an exaggeration, it is one of common occurrence. I always give long exposures for such subjects, to prevent ghosts.

I often wish to introduce figures, but this requires the greatest caution, for if the crowd catches the idea, off they all go to be taken; in that case it is useless to interfere, for a crowd collects which takes a long time to disperse. To get rid of a crowd I am often obliged to take away the camera, and come back again when the place is clear. Sometimes I am annoyed by troublesome people who will persist in being taken; I then put on an appearance of indifference, as though it was all over, and so tire them out; it is useless to attempt to take them, for they invariably move on during the exposure if not asked to be still. When an opportunity occurs of working from a first floor window, it is a great treat. I generally acknowledge this favour by sending some photographs. I was once tendering my thanks in this way, when I was curtly informed that was an old story, and one never fulfilled; the price was five shillings, which I paid, with thanks for the accommodation.

I will now describe my apparatus. The camera-stand I use is a very old form, lately resuscitated, I think, by myself. Mr. Ayers lent me his, which I liked so much that I got Messrs. Oakley to make me two, and advised him to make them for sale. He did so, and had a block cut, which he registered, and many thought he had registered this old form of stand, but it was only the wood-cut. I find it most useful having a range from three feet to six, allowing of its being used very low when doing a flat tomb. It allows of adjustment in the most awkward positions in the roof of a house, in the seats or stalls of a church, when doing interiors. I now often wonder how I did without it so long.

I never use a swing-back, for various reasons. It prevents the camera (the form I use) from closing sufficient for the shortest focus-lenses; it adds to the bulk and expense. I find the sliding front answers every purpose. I have an additional piece hinged on the front, which allows of its

going up any height. This arrangement would not do for the old form of lenses of large diameter and small field. The small diameter of the symmetrical lenses is a move in the right direction—portability and lightness combined—evidently the result of the studies of a practical man. One flange answers for a stereoscopic lens, or one covering a twenty-inch plate. With the sliding front I can succeed in taking a building at an angle of forty-five degrees. This brings the subject almost close to the circle of definition. Blocking out the sky, of course, is necessary. By reversing the camera front I am enabled to photograph from an elevation, and still keep the camera perfectly level. This is very important for flat tombs in confined situations. I invariably keep the camera quite level.

To keep the camera-stand steady when windy, I have improved on the old idea of the loop for placing the foot in and bearing heavily on it, by introducing an india-rubber door spring, which allows the foot to remain firm on the ground, instead of moving, and, perhaps, doing what you are anxious to avoid.

I will now go from the streets into some of the most difficult interiors. The Houses of Parliament, Tower, and Temple are the worst, requiring exposures of nearly two hours. Two negatives a day and four cameras at work is a fair average. All sorts of exposures are necessary in Westminster Abbey, from half an hour to two hours. St. Paul's the same.

My experience with interiors varies considerably. One year I found that plates kept in the bath nearly half an hour answered the best; another year I found it the very opposite, from which I conclude it is almost impossible to work to any rule, as it depends in a great measure upon the particular kind of collodion in use at the time. I find it important to use a new bath of forty grains to the ounce, with as little acid as possible, old collodion, with the addition of one or two grains of bromide to the ounce, and strong developer; to use albumenized plates, plenty of blotting-paper, and to keep the backs well sponged out and varnished where the plates touch, and to fix thick brown paper saturated with water on the back of the plate and at the bottom of the camera.

My old enemies, the public, follow me even into sacred places. With exposures of an hour you cannot sit down beside the camera, so I work two; well, on returning to develop, imagine with horror an anxious mother gratifying her offspring's curiosity by lifting up the child to peep into the lens, the youngster steadying himself by holding on to the lens; or an indulgent papa gratifying his little girl by lifting her up to play an imaginary tune with the focussing handle of the camera.

VENTILATION OF PHOTOGRAPHIC STUDIOS.

BY JOHN LAING, F.R.S.S.A.*

In bringing the subject of this paper before the members of the Edinburgh Photographic Society, it is with the view of correcting an evil which, to a very great extent, exists in our midst. It is on the subject of ventilation of studios that I would wish to say a few words. Photographers, it would appear, seem to have a great dread of fitting up a ventilating apparatus in connection with their studios, and more especially in their dark rooms. I have heard various reasons for such non-appliance of a ventilating apparatus. One of them is, that white light would come in and spoil all their work, and thus become a great source of vexation and annoyance. Another reason is, that any down draught which might occur (they very often occur in the general forms of ventilating systems) would raise the dust from the floor and furniture connected with the studio, and while thus floating suspended in the atmosphere of the place, wet plates

would come in for a great share of the mischief which would thus be caused; and to prevent all this photographers would rather suffer an ill-ventilated studio than have all their best efforts spoiled by that inveterate photographer's enemy, "dust."

How often do we see those much engaged in the dark-room operations, when they come into the lightest apartment, wiping the sweat from off their foreheads, and altogether looking as if they were glad to enter a better and more wholesome atmosphere!

There is no doubt that some of our studios are very badly ventilated (if ventilated at all), and this is why there is such a strong smell of sulphuric ether (which is present in the collodion) in those studios, and which, though a characteristic of the profession, yet is very offensive to delicate constitutions, and ladies more particularly. I once met with a lady who had just returned from such a studio, and who went with the intention of getting photographed; but on entering the establishment the "etherial perfume" was so strong and overpowering that she nearly fainted, and had to get cold water applied to her in the manner generally employed when people are in a fainting condition. When she came to herself again, she got into a cab, and drove home; and when I saw her she vowed she would never again enter a photographic establishment; and she has held such places in awful dread ever since.

Now if we had a complete system of ventilation in our studios such accidents would never occur, and the benefit in point of health would be great to all concerned, and more particularly to those who are much engaged in the dark room operations. Such people run a great risk of injury to health. It may not come upon them suddenly, but, nevertheless, its slow progress is not to be overlooked and unheeded. I have actually heard a photographer express himself, when I called to see him, that "he felt his head quite muddled;" and this, undoubtedly, was due to the stifling condition of the atmosphere he was breathing.

I won't say that all studios are alike—far from it—for there are some which I have been in which, on the whole, are well ventilated. Some are ventilated by a current of air being made to pass freely through their studios in the form of a draught, by having two opposite windows, or other opening freely open, and thus causing a draught; but this method of clearing a place is very objectionable from a health point of view.

Now what we want is a complete and continuous ventilation; by that I mean, to have the foul or impure air drawn off as soon as formed, and this without a down draught.

Now there is only one system of ventilation at present in operation that I know of which can bring about this desired end, and that system is the one patented by Messrs R. Boyle and Son, of Glasgow, and which they call "Boyle's Patent Self-acting Air-pump Ventilation." They have no movement in them, and therefore cannot get out of order. They continue to be ventilators as long as the metal holds together, and they are just as efficient in their action as ventilators after they have been up for twenty years as the first day in which they were put up. They are neat in appearance, and can be made to any pattern or design of an architect, and you will see by their price lists they will stand a very favourable comparison in price with any form or system of ventilation now in existence. There are various systems adapted to studios, but they are all more or less inefficient and unreliable. Those which have a movement in them are objectionable, for should they get out of order (as they frequently do), the effect is anything but pleasant. I will only here refer to the Archimedian screw, which we see so often applied to studios and other buildings.

This apparatus is at any time liable to a down draught, and, when such takes place, a continuous down-pour of cold air, sometimes accompanied by rain and soot, and all

* Read before the Edinburgh Photographic Society.

other impurities which are to be found contained in the atmosphere at the house tops. It likewise makes a disagreeable noise at times, to the great annoyance and irritation of all who are unfortunate enough to be within hearing. Its appearance, also, is not in its favour. From its construction it cannot be made more ornamental unless by materially interfering with its efficient action. Mr. Boyle informs me that they have had to remove a great many of them on account of the down draught which they admitted; and they replaced them with their own system, and the air-pump ventilators gave undoubted satisfaction. The syphon ventilator is quite useless as a ventilator. Any system which allows cold air in from above must be condemned, because this cold air coming in cools down the heated and vitiated air naturally found at the ceiling, and this, losing its upward force, is again returned to the apartment, to be again inhaled; and though we are getting cool air, yet we are not getting pure air, which is a great matter, and a point often overlooked, though it is worthy of our best and immediate attention. The ventilation by means of running a pipe into a smoke flue is very objectionable on account of the back draught and disagreeable smell which it produces; and besides this the soot coming into the apartment would spoil everything in the place, and picture frames would soon require re-gilding. Such was the case with John Stirling, Esq., Governor of North Prison, Glasgow, who had his house so ventilated; and Mr. Boyle had to undo the whole system and fit up his own, and Mr. Stirling is quite delighted with the agreeable change that has been brought about.

The air-pump ventilators consist of four sections, each acting independently of the other; the external air impinging on the lower plates (or diaphragms) is deflected at different angles over the central radial plates, and in passing out exhausts the internal chambers, creating a partial vacuum. The foul air immediately rushes up the shaft (connecting the ventilator with the place being ventilated) to supply the place of the air extracted, thus securing a continuous powerful upward current, and no down draught. For studios on the ground floor, with higher buildings around them, they are generally subject to a down draught, owing to the wind striking the higher buildings, and then forced downward with a swirl, and the studio is the place where it is most felt, by its being on the lower ground. Now, for this position of affairs, Messrs. R. Boyle and Son have a modification of this patent, which is entirely impervious to down draught; and such positions as on the top of these studios is the very best place for its efficient action. It is not intended so much to create an up draught, as to entirely prevent a down draught. I have no personal interest in the concern whatever. I only take it up on scientific grounds, and I can only say that if once applied, great will be the satisfaction to all concerned.

In conclusion, I can only say that Messrs. Boyle and Son deserve every credit and encouragement for the useful invention which they have produced, and I have no doubt that before long they will reap the harvest which they so justly merit.

HOW TO PAINT CHROMO-PHOTOGRAPHS.

BY W. F. ASHLE.*

AFTER mounting your print face down on the concave side of the glass, rub over the back with lard (you will then see the picture come out like a transparent positive) and allow it to stand a few minutes, so that the grease can penetrate all the pores and fibres of the paper. Now it is ready for painting. Paint the shadows under the eyebrows with burnt sienna, and the whites of the eyes with silver white. Use cobalt blue for blue eyes, and burnt

sienna for brown eyes. Mix Naples yellow and silver white for the high lights of flesh colour; mix light English vermilion, Naples yellow, and silver white for the dark flesh tints. Use pure vermilion in the centre of the cheek, softened out with flesh colour, and pure vermilion for the lips; for the ears, dark pink. For light brown hair, use raw sienna (if very light, add Naples yellow); for dark brown add burnt umber, also burnt sienna for warm hair. Use king's yellow for all bright yellows (gold, &c.), cobalt blue for all medium blues, adding silver white for light blues, Prussian blue for all dark blues, and emerald green for all light greens; mix Prussian blue and raw sienna for dark greens, adding king's yellow for yellow light greens. Use burnt sienna for browns, adding raw sienna to make a change; carmine for crimson, adding white for pink. Mix carmine and cobalt blue to make dark purples, adding silver white for light purples; use vermilion for scarlet, adding carmine for a change. King's yellow and vermilion make orange. Mix black, white, and red in different proportions to make all greys. Paint all whites with silver white; the dark shades only of black drapery with ivory black.

My experience teaches me that lard gives the most transparency; and paper having more affinity for it than anything else, it is not likely to become opaque.

AN ELECTRIC CANDLE.*

The value of electricity as a source of artificial light has always been recognised, and its utilization has frequently been attempted. The great obstacle, however, which has hitherto prevented the practical attainment of this object is the difficulty of subdividing an electric current, and producing a number of lights from one main source. This subdivision of the current, as it flows from the generator, has several times been attempted, and in some cases—experimentally, at least—it has been attended with success. The fine carbon points were, however, quickly consumed when burnt in contact with oxygen, and thin platinum wires melted as soon as they began to give a perfect light, and, so far as we are aware, no system of subdivision of electricity has come into practical operation.

About the first who attempted to solve the problem was M. Lodyghin, of St. Petersburg, who, some few years since, used a vacuum, burning the carbon out of contact with the oxygen of the atmosphere. The details of his apparatus, however, were imperfectly worked out, and failure resulted.

M. Kosloff then took up M. Lodyghin's idea, and in time succeeded in producing an efficient means of subdividing the electric light. By forming the holders for the carbon points of a special metal, and producing the light in a vacuum lamp, excellent results were produced.

M. Kosloff's apparatus was exhibited in London in May, 1874, and some very successful trials were made with it, and reported upon by us at the time. It does not, however, appear that this invention went beyond the phase of experiment, at least in England, although it was an invention of great promise. Hence, wherever electricity has been utilized, as in lighthouses and for signalling or other purposes, the constant shortening of the carbon points by combustion has to be compensated for, and followed up by clockwork, so that the necessary distance between the points is preserved as nearly uniform as possible.

It has remained for another Russian man of science—M. Paul Jablockhoff, who was formerly in the Russian military service—to demonstrate in practice the feasibility of subdividing the electric current. He has worked out his results in the form of an electric candle, which governs the production of the electric light, and supersedes the ordinary clockwork arrangement. By it he has, moreover, demon-

strated the possibility of obtaining several lights from a single source of electricity.

The first practical trial of this system was made a fortnight ago at the Magasins du Louvre, and the experiments were attended with perfect success. The Marengo Hall was the apartment lighted, and six electric candles were sufficient to shed around a very bright light, which was softened by being transmitted through opal glass globes. Some idea of the comparative value of gas and the electric light under notice may be formed when we state that the Marengo Hall is ordinarily illuminated by means of one hundred argand gas burners of the largest size. The cause of the wide difference between this and other electric lights lies in the fact that electricity plays, so to speak, only a secondary part in producing the light. The light is principally the result of the combustion of the refracting material, which occupies in the electric candle the same position as does wax or tallow in ordinary candles.

The electric candle, as originally designed by M. Jablockhoff, consisted of what may be termed a double wick and a surrounding material. The wick consisted of two carbon points, about four inches long, embedded parallel to each other in an insulating substance, by which also they were separated from each other. This material, which was consumed as well as the double wick, was composed of several ingredients, forming a combination known only to the inventor. Each of the carbon points terminated at the bottom in a small metal tube into which the conducting wires were led. With these candles a series of experiments was some time since carried out by a War Office Committee of Royal Engineers at Chatham. It was then demonstrated as one result that the system gave fifty per cent. greater power of light than had ever before been obtained from any electric light. The next development of the electric candle by M. Jablockhoff was to denude it of its outer casing, leaving merely the double wick with a strip of the insulating compound between the carbon points, which terminated at the bottom in metallic tubes, as before. It was with the electric candle in this form that the hall at the Magasins du Louvre was illuminated, as previously stated. In either case only one electrical machine is needed to produce a number of lights. The positive and negative wires are led from the machine, and branch wires are simply conducted from them at the necessary points to the candles. In this way M. Jablockhoff succeeded in getting as many as eight candles to burn at the same time in the circuit of a single machine of the ordinary kind, with alternating currents.

Arrangements are being made in England to light up one of the East and West India Dock Company's docks in London upon M. Jablockhoff's system, so that the loading and unloading of ships may be carried on by night as well as by day when desirable. Experiments were to have been primarily made in order to test the system, but since the exhibition of the electric candle at the Louvre, M. Jablockhoff has still further improved his system, so that the experiments have been postponed for the completion of the details of the improvement. In the new form of candle the inventor dispenses with the carbon points which constituted the wick, and uses only the outer surrounding material answering to the tallow of an ordinary candle. We have already seen that this compound—to which M. Jablockhoff has given the name of "kaolin," which substance enters largely into its composition—consumes at the same rate as the carbon points. From this material alone M. Jablockhoff now produces results superior in many respects to those which he previously obtained. One point of superiority consists in the fact that he is now enabled to produce as many as fifty constant and uniform lights from a single machine of the ordinary kind, as was recently stated in a paper brought before the Academy of Sciences, in Paris, by M. Dumas. In short, M. Jablockhoff appears to have satisfactorily solved the question of dividing up the electric light by a method capable of practical application,

of insuring perfect steadiness in the light so divided, and of distributing throughout a building lights of varying degrees of intensity. These results point to a very wide application of the system, which appears to possess special advantages for the lighting up of theatres and other large buildings. The application of the invention is being brought out in Paris by a company, of which M. Denayrouze is the manager, the agent in England for the invention being Mr. R. Applegarth, of 7, Southampton Street, Strand.

A NEW CARBON PHOTOMETER.

BY E. K. HOUGH.*

A SHORT time since, in your pages, Mr. Loeffler suggested using four or more different timed negative impressions of the same face as a photometric guide in carbon printing.

Undoubtedly the first stumbling-block of hindrance to the adoption of carbon printing is the invisibility of the image, and the necessity of timing the exposures. Any method of attaining greater certainty and uniformity in that is worthy of consideration. That difficulty seems much greater to a printer already trained to the methods in silver than it would to an entirely new beginner in carbon; and my short experience inclines me to believe that a new beginner will learn to time by the usual meter as quick, if not quicker, than by one made of negatives. But as most of the printers who undertake carbon are trained to judge by the gradually deepening shades of the face, I will describe one I have made as an improvement on Mr. Loeffler's original suggestion.

I made a row of half-inch negative heads, with five seconds' exposures to each, across a 4-4 plate about half an inch above the centre, so that when the hinged back of the printing frame is half open it shows the entire line of faces above. On the back of the glass, over the line of faces—which are numbered from one to ten at the side of each face—I placed strips of mineral paper, the first covering all, the next all but No. 2, and so on till No. 10 has ten thicknesses; a clear glass over all, sealed to the first, protects the paper, and finally the whole is covered with non-actinic paper on both sides, except a strip half an inch in width over the faces. To use, I put in the lower half of frame a sheet of sensitive paper five inches square, or narrower, if only a portion of meter range is to be used. When the first exposure is made and frame opened, the entire line of faces, with their graduated depth of shading, is visible at once, with the same light on each. When pulled up half an inch, and the second exposure made, the first line of faces remains as a guide for the second; and so on until the eight or nine possible exposures are made, giving the great advantage of having all the previous exposures before you in each as a corrective to any variations, thus offering a better guarantee of uniformity than by comparing each time with the one last printed only, or even to a standard strip of graduated tints fixed in the frame as a permanent guide—a strip of toned prints from the faces, for instance.

The same principle might be applied to the old meter with graduated tints on a plane surface, and would avoid much of the difficulty that caused Mr. Loeffler to devise the negative meter. For instance, if while the proof was printing the meter showed to five, and none beyond, the assistant could be told to print the first carbon so far and no further, and then continue so that the rows of tints—which need not be more than one quarter of an inch wide—increased before him at each successive exposure, he could easily see if was keeping an uniform line of shading, as easy if not more easily than with a line of faces. Either method constitutes a genuine improvement on the old system, according to my experience.

THE SILVER BATH: ITS DEFECTS AND REMEDIES.

A PROTRACTED discussion on the silver bath, continued during several meetings of the Photographic Society, concluded on Tuesday evening, without, we think, throwing any new light on the subject. It served the useful purpose, however, of bringing in review many known methods of dealing with difficulties, and of assigning to many of them their proper functions. The chief defect under consideration was the tendency in the bath to give negatives covered with pinholes. This has generally been attributed to the supersaturation of the negative bath with iodide of silver; and one result of the discussion was to recognize the operation of other causes in producing pinholes. Indeed, the tendency of the discussion was frequently towards a recognition of other causes, ignoring, to a considerable extent, the operation of this most prolific cause of the trouble in question.

That excess of iodide of silver is the most common cause of pinholes there can be little doubt. A most perfect crop of pinholes can be produced at will by adding excess of iodide of potassium to a silver bath, so as to supersaturate it with iodide of silver. This being so, and the ordinary mode of working a silver bath tending to produce supersaturation, the eventual advent of pinholes from the continued use of a bath becomes, under ordinary circumstances, inevitable. The solution is supplied with iodide of silver to begin with, and if not saturated at the outset, it acquires more from every plate immersed, until the point of saturation is reached. So long as this condition of saturation only is maintained, all is well. But the varying conditions to which the bath is subject inevitably bring about the state of supersaturation. For instance, iodide of silver is less soluble in a warm solution than a cold one, and as the temperature rises on a hot summer's day, the solution which in the morning was simply saturated, becomes supersaturated by its solvent power becoming less. Then it happens that the slightest disturbance of the molecular condition—such as the immersion of a plate—produces a precipitate, and the surface of the plate receives a deposit of the minute crystals of the salt present in excess, and pinholes are the result. A similar result will ensue without any variation in temperature. Iodide of silver is soluble in a solution of nitrate of silver in direct proportion to the strength of that solution. When, therefore, a single grain of nitrate of silver is removed from a solution saturated with iodide, its solvent power is reduced. It must be borne in mind that in the operation of sensitizing a collodion plate silver is removed from the bath, and the solution in immediate contact with the collodion film is weakened in proportion,

and loses, therefore, the power to hold in solution the iodide it held a moment before; hence the salt in excess is deposited on the plate in minute crystals, which issue in pinholes. This is a process perpetually going on wherever the ordinary wet collodion process is worked. To avoid the ready occurrence of the conditions producing these pinholes, it will be found wise to work with a full quantity of solution, which will not readily become exhausted; keep up the strength by addition from time to time of fresh solution, and in summer weather keep the silver solution cool. The remedy for such pinholes is dilution of the bath, filtration, and strengthening.

A very common cause of pinholes and similar defects is often overlooked, because it is obvious. We refer to dust, dirt, or foreign matter of any kind in the bath. A plate was exhibited the other night at the meeting of the Society, by Mr. Dunmore, which was covered with pinholes, streaks, and comet-like markings. To the suggestion that the defects were caused by dust, Mr. Dunmore returned the natural answer that as the work was done out in a field where there was no dust, and camera and dark slide were quite clean, he did not think it could be dust. But the appearance of the plate suggested not dust in the form of dust, but a residue of dust or similar particles in the bath, which, being stirred up, would produce just such a result as that shown. The remedy applied with success is confirmatory of this view. Strengthening the bath by the addition of fresh solution effected a cure at once. It is probable that when fresh solution was added the bath was filtered, and the turbid residue removed. To avoid the risk of such spots the use of a dipper which does not permit the plate to go to the bottom of the bath is desirable.

One valuable result of the discussion has been to assign to nitrate of baryta, a remedy much talked about of late, its proper office. It is valuable in removing pinholes when caused by the presence of sulphate of silver in the bath; and the presence of this sulphate in the bath appears to be much more common than was suspected. According to Mr. Spiller, who has investigated with great care, and to whom photographers are in this matter much indebted, almost every example of iodide of potassium he examined was contaminated in greater or less degree with sulphate of potash. The use of iodides so contaminated is probably the most common source of sulphates in the bath. This fact, and the use of nitrate of baryta as a remedy, were, as our readers know, pointed out by Dr. Vogel in our pages many years ago; and we kept the remedy under the attention of photographers in these pages and our YEAR-BOOKS at intervals afterwards. Unfortunately the use of this salt was revived a few years ago as an empirical remedy for pinholes generally, and caused disappointment by its inevitable failure to be of service when applied to baths in which sulphate of silver was not the cause of the defect. Mr. Spiller's experiments, definitely assigning to the baryta salt its special role, which had been by many unrecognized, have been of marked service here.

One of the most interesting elements in the discussion was the introduction at the last moment of Mr. F. G. Eliot's method of working an alkaline silver bath. Upwards of two years ago, in our YEAR-BOOK for 1875, Mr. Eliot described his method, and again in the YEAR-BOOK for 1876 gave the result of continued experience. His method consisted in saturating his nitrate bath with carbonate of silver, instead of adding iodide of silver. A little carbonate of soda was added to the new bath, and the precipitate removed by filtration. As carbonate of silver is slightly soluble in a solution of nitrate of silver, a portion of the carbonate of silver is retained in solution in the bath. The solubility of this salt in a solution of nitrate of silver was questioned at the meeting on Tuesday evening. But a little experiment will determine the question beyond doubt. Carbonate of silver is soluble in water in a slight degree, and still more so in a solution of nitrate of silver, which

shows a marked alkaline reaction after treatment with the carbonate. To work with this bath Mr. Eliot uses a collodion prepared with bromides and iodides of cadmium and potassium sufficiently ripe to have liberated sufficient iodine to produce a lemon colour in the collodion. This trace of free iodine, on combining with nitrate of silver, liberates a trace of nitric acid in immediate contact with the film, and this appears sufficient to check all tendency to fog, which, from the alkaline condition of the bath, might be expected. The advantages Mr. Eliot finds in this method are complete immunity from pinholes, streaks, fog, and the various troubles with which photographers generally are only too familiar, as well as greater sensitiveness, and a finer class of negative. Confirmation is not wanting, although few photographers seem to have had the courage to try an alkaline negative bath. Mr. Spiller mentioned the experience of Mr. Bashford, of Portobello, as very similar. We have heard Mr. Blanchard describe his successful use of a bath treated with carbonate of soda without any subsequent addition of acid. Mr. W. Brooks described similar experience recently. The experiment is a simple one, and, on the successful practice of several capable photographers, we can recommend a trial to our readers.

LICHTDRUCK IN GERMANY.

ALTHOUGH M. Tessié du Motay et Maréchal, of Metz, were undoubtedly the first to produce presentable half-tone prints from a colloid film, Germany has since then been pre-eminently to the fore in Lichtdruck printing. MM. Tessié du Motay et Maréchal proved the method to be sound and practical, but under their auspices it was impossible to provide a gelatine printing block from which more than seventy or eighty impressions could be pulled. Some examples of their work which we have seen show a very high state of perfection indeed, the delicacy and gradation of the impressions leaving little to be desired, and bearing advantageous comparison with proofs that have been produced in later years. In fact, it was simply in the perishable nature of the printing blocks that the weakness of the process lay, and to obviate this was the aim of German experimenters who have since striven, and with considerable success, to perfect the process of colloid printing.

Albotype was the method which, after that of Tessié du Motay et Metz, acquired the greatest reputation. Then there was the method of Ohm and Grossman, who were the first, we believe, to bestow the name of Lichtdruck upon colloid printing; Obernetter, of Munich; Husnik, of Vienna; and in this country Mr. Edwards, who called his particular method by the name of Heliotype. All these processes, as our readers are aware, have much in common with that of the French photographers to whom we have referred, but one and all permit of a far larger number of impressions being taken from a single plate.

None of the processes are now worked in the same manner as when first brought before the public half-a-dozen years ago. Albotype, though in many respects a most perfect method, had one very great defect. Thick and costly glass plates formed the basis of the printing-blocks, and the great pressure to which these are subjected in printing caused heavy loss from constant breakage. Again, the gelatine film, with all the precautions at first used, could not be made to adhere sufficiently tight to the glass surface. Albert, it may be remembered, printed through the back of the glass plate, in order to secure an insoluble film next the glass surface; but even this *modus operandi* failed to secure the solidity necessary. By degrees, however, the process of Lichtdruck printing has been greatly improved, and it is, as we have said, due for the most part to German experimenters that we have now arrived at a very high degree of perfection in colloid printing.

Among those of our German cousins who have laboured hard in this particular branch of photography may be mentioned Professor J. Husnik, of Prague, who is not only a practical chemist and photographer, but a painter of some note into the bargain. Herr Husnik's name is well known as an experimenter in photographic chemistry, and, as he tells us in a volume which he has just published on Lichtdruck, has been practically engaged since the year 1861 upon various methods of photo-mechanical printing. Herr Albert has been a student of his, as many other German photographers of note, a pretty good proof that the Professor is well qualified to speak upon the subject on which he has just written. In a few preliminary remarks he informs us that the information he has published is the result of many years' experience, acquired partly in the State Printing Office at Vienna, and partly at private printing establishments, among others those of Albert, Obernetter, Loewy, &c. His volume consists of one hundred and sixty closely printed pages, and although only the first half of the book deals with the actual preparation of Lichtdruck blocks, &c., the whole may be read with interest by those interested in mechanical printing generally.

We shall, at an early opportunity, give our readers some extracts from Professor Husnik's work, and detail at length the manipulations connected with Lichtdruck as it stands in its most approved form. So that all classes of readers may be satisfied, Herr Husnik first of all gives precise details of the methods followed by Albert, Ohm and Grossman, and others, prior to giving information of his own improved process. He points out the defects and difficulties of all the earlier methods, and shows how these may be overcome, referring especially to the use of silicate, which seems to exert a material benefit in colloid printing. That very perfect prints may be produced by the Albert process, Herr Husnik readily admits; but the employment of glass plates, the elaborate preliminary preparation of the blocks, and double exposures to light that are necessary—matters which increase in difficulty in dark and wintry weather—have stood in the way of its diffusion.

To render the blocks more stable, without having recourse to the laborious manipulations necessary in Albotype, as also to produce a smoother and more uniform gelatine layer, are matters to which attention has been directed of late. The first idea of employing silicate to harden the film and make it adhere more tenaciously to its basis emanates, it appears, from Herr Obernetter, of Munich, although for a long time its use in Lichtdruck was maintained a secret. Soluble silica has been found especially useful, we are told, and the fine Lichtdruck prints which have come to us from Munich and Vienna, where silica is employed in Lichtdruck printing, place the fact beyond a doubt. Another improvement which has contributed to perfect the process is the employment of a solution of gelatine containing alcohol, which is finally poured over the gelatine slab. Minute air-bubbles form, it appears, upon the surface, and these, bursting, create minute depressions, which appear in the finished prints as dark spots. Such defects are at once avoided by the use of an alcoholic gelatine solution, which has the effect, moreover, of producing a block of very uniform thickness. Again, there is no need for drying in a horizontal position (a matter of the utmost difficulty), for Herr Husnik explains that the gelatine plates prepared according to his instructions may be put upon a slope to dry.

It is these last-mentioned improvements to which Herr Husnik calls especial attention, and upon which depends, in his opinion, success in Lichtdruck printing. They render the process at once certain and practical, and fairly bring it out of the domain of experiment into that of industry. We shall take an early opportunity of placing Herr Husnik's perfected Lichtdruck process before our readers.

FRENCH CORRESPONDENCE.

A DRYING CUPBOARD—A NEW TRANSPARENCY TISSUE FROM SEA-WEED—HOW TO PRODUCE STIPPLE FOR PHOTO MECHANICAL PRINTING—REUNION DES PHOTOGRAPHES A PARIS—RECTIFICATION.

At the monthly meeting of the French Photographic Society, which took place on Friday, 4th May, M. Harrison, fils, exhibited a drying cupboard of a very ingenious character. It is a very simple affair, while at the same time it suggested more than one useful application. Briefly described, it is a box (which may be large or small) furnished with horizontal grooves inside, or, more properly speaking, a cupboard in which the shelves are replaced by glass plates held only by one of their extremities in the grooves. The first, for instance, is kept in its place by the right wall of the cupboard, and the second by the left wall; the third again on the right, and so on from top to bottom. As the plates are not so large as the box, there is always between their ends and the walls of the cupboard a certain interval as shown in the annexed figure.

The cupboard is closed by a hinged screen which acts like the door of a chest, having, however, double sheets of metal, between which a lamp may be introduced. The warm air having circulated by the winding passage formed by the plates escapes through an opening made at the top of the drying cupboard, and which is surmounted by a chimney contrived so as to establish a good draft of air. The draft may be augmented by placing a small lamp or night light by the chimney. The drying cupboard is very simple, practical, and inexpensive, so that altogether M. Harrison's contribution to the Society was well received, and especially by those members who occupy themselves with carbon printing, for it is obvious that the cupboard in question is very suitable for the drying of plates and tissue.

A communication which appeared very interesting was made by M. Stenfort, an amateur who has hitherto occupied himself more with botany than with photography. In the course of certain scientific researches M. Stenfort became engaged in the work of reducing marine algae to the state of a very fine powder, which he dissolved and converted into a tissue by drying, several specimens of the same being submitted by him. The sheets which we examined looked very much like sheets of gelatine or collodion, by reason of their transparent nature, but they had all the suppleness of silk, were not elastic, and were exceedingly tough when it was sought to tear them. They seemed to possess all the qualities which are sought for in a photographic film, without the inconveniences of many substances hitherto proposed. Moreover, such films may be tinted to any colour that may be desirable. M. Stenfort stated that the tissue in question can be employed for lithographic transports, and indeed this is, so far, the only trial he has made of the material upon his own account. He thinks, however, that some use may perhaps be made of the material for fatty ink printing, and in other branches of photographic industry. Many of the

members of the French Photographic Society who examined this algae tissue were of opinion that uses could be found for it, and especially in carbon printing. M. Davanne was of opinion that this organic substance might be made to replace gelatine and even collodion. Most of those present begged for a sample of the material to experiment with it. It may be well to add that employment of algae powder would have economy to recommend it, since the preparation of a sheet of the material costs but a few centimes. I shall take care to keep the readers of the PHOTOGRAPHIC NEWS posted up in any results that may be arrived at.

M. Despaquis has communicated to me a method of typography which he has not yet altogether made known, and which he has already practised with considerable success. A positive is taken upon paper, or upon glass, from which is produced in the camera an enlarged negative, reducing according to the wish of the operator. In the passage of the luminous rays, and as near as possible to the collodion plate, is put another sensitized plate, upon which is some very fine powdered plumbago, applied by the aid of a fine piece of linen or delicate sieve. This powder, while very tenacious, is very opaque, and the consequence is that one secures a negative covered with very minute spots both in the lights and in the shadows. A positive impression upon metal is secured by the bitumen process, or by greasy ink, developing a print upon the surface by the aid of carbon tissue made with graver's varnish. This impression exhibits all the tiny holes with which the cliché is covered; etching acid applied, attacks the metal where these tiny openings occur, and the result is a block engraved in relief, from which prints may be pulled in a type press, giving detail and half-tones of the original. This same means—viz., the interposition of a powder screen—may be employed for transferring images upon stone and zinc, the inking-up of the transfer being in this way greatly facilitated.

At the end of the dinner of which I spoke in my last letter, and at the meeting which followed it, it was decided to rent for the Wednesday evening of every week a saloon attached to the Brasserie de Metz, situated No. 6, Place de Valois (Palais Royal), and that all gentlemen connected with the art and industry of photography should be invited to meet there at the time mentioned. Professional and amateur photographers, as well from Paris as from the Provinces, will be found here, so that visitors and strangers spending any time in Paris will know where to meet their confrères in social reunion once a week. The arrangement is for no other purpose than to establish a spot where all can meet on neutral ground, and where they can have the benefit of one another's company, and discuss questions of especial interest to themselves. A very moderate subscription will suffice to cover the trifling outlay that will be necessary, but the amount will not be fixed until more definite regulations are made. I need not state that when any of the readers of the PHOTOGRAPHIC NEWS find themselves in Paris, they will find a most sympathetic welcome at the Reunion des Photographes, if they will present themselves on Wednesdays at the address I have mentioned.

The Municipal Council of the town of Chalon-sur-Saône have just voted the sum of 5,000 francs to erect a statue of Nicéphore Niepce in his native place. It is rather a tardy testimony to the worth of their fellow-citizen, for poor Nicéphore died as far back as 1833.

I see in your last issue of the PHOTOGRAPHIC NEWS that a paper by M. Boivin was stated to have been read before the French Photographic Society. May I be permitted to say that it first appeared in the *Moniteur*, and was not brought under the attention of the Society in question.

ERNEST LACAN.

Correspondence.

WHAT FOLKS ARE SAYING.

THAT the Glasgow Association propose to send Messrs. Urie and Robertson to Coventry.

That the Edinburgh Society propose sending Dr. Nicol to Aberdeen once a month for wrinkles.

That they don't know the difference between G. W. Wilson and Co.'s carbon enlargements, and Annan and Skelton's autotypes.

That the Autotype Company are experts, and will soon tell

That the old carbonist, Tunny, of Edinburgh, has become a chromotyper.

That some more of the best men in Scotland will come over to the carbon camp soon.

That the best means of introducing chromotype to the public is not yet hit on.

That non-licenceses taboo permanent photography.

That they want to know how the *permanence* of a new process is tested.

That ye of "this carboniferous era" ought to educate the public.

That there are too many good men and true troubling themselves about the patents and the pound.

That good men will cease from troubling, and silver will be at rest.

That W. E. Batho is trying to damn carbon with faint praise.

That the "Peripatetic Photographer" is always telling us of his fear to discuss matters of religious belief, and of Sunday photography.

That the "Peripatetic" should give his opinion of "secular business on Sunday."

That Gustave Konigsberger is saying, "I'll mark out 'Murray Russell,' by George!"

That "Ja Vestris" is a two-headed nightingale, spotted here and there.—Yours truly,
JANUS.

MAGNETO-PHOTOS.

DEAR SIR,—My attention has been called to an article which you have reprinted in your issue of May 4th of the PHOTOGRAPHIC NEWS, from the *Scientific American*, respecting the statements that I made at the March meeting of the South London Photographic Society, on so-called magneto-photography. I thank the writer of that article for re-describing my statement. The first part I have nothing to find fault with. The latter part is not correct, for if he reads again, he will find the probable cause why the whole of the letters did not appear—simply because the greater part of the letters had been destroyed by the way I applied the Indian-ink. I use the words magneto-photograph for the want of a better way of expressing myself. I am well aware of the so called *od* light that is invisible to the human eye, and am also aware of its being associated with several things in nature, and also its effect on people as well as sensitive plates; but I find it more strong by developed or associated with the magnet than anything else I have at present tried.

As for the printed letters making their appearance, I cannot account for that, but it appears to me that it was a secondary action of some kind or other set up. I think it very *od*(d) that our friend did not read the latter part of my communication right. I know it has been a difficulty with scientific men to prove that there is photographic action set up. Since I brought the subject forward I have been able to bring it so under control that I can get an image every time with the exposure of two or three minutes, and I fully intend to bring it forward, and be able to expose and develop a plate before the South London Photographic Society. I also take the opportunity to make a further

statement, and that is, I think it *one* cause of the so-called red fog that makes its appearance at times, which originates with the operator himself. If our friend will wait patiently I will deal with that part of the subject, and be able to bring it forward as a fact. I have very strong grounds for introducing this here.

To finish up, he says he thinks I am a *medium*. Most likely I am; and I think we all are *mediums* for imparting any information on any subject that we may be investigating. It is a pity he did not explain himself more fully. I will conclude by returning the compliment. In all probability he may be a *medium* under the control of a very powerful spirit well known in England as "Old Jamaica."—Yours very truly,

WM. BROOKS.

Proceedings of Societies.

PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN.

THE usual monthly meeting of this Society was held in the Water Colour Gallery, 5, Pall Mall, on the evening of Tuesday, May 8th, Mr. J. GLAISHER, F.R.S., in the chair. The minutes of a preceding meeting having been read and confirmed, Mr. C. G. Cutcher was duly elected a member.

The CHAIRMAN, after announcing that the discussion on the nitrate bath would be resumed, remarked that Col. Wortley was still unable, from indisposition, to attend, but he had sent a note on the subject, which the Honorary Secretary would now read.

Mr. H. BADEN PRITCHARD then read the following note from Col. Stuart Wortley:—"During a visit to the Autotype Company's Works, last summer, Mr. J. Burton called my attention to a deposit which he found in their silver baths, and of which he was good enough to give me a specimen for examination. Having applied various tests, with a view of discovering the nature of the salt, I informed Messrs. Burton and Wilkinson, at the November meeting of the Photographic Society, that this deposit consisted of sulphate of silver. As I was desirous of finding how and why sulphate of silver appeared so freely in a negative bath, I made the following experiment to see whether it was produced by the collodion:—I took plain collodion, and poured it gradually, stirring it all the time, into boiling water, and after allowing the precipitated pyroxyline to soak for a short time, drained off the water, and having added to it a small quantity of strong solution of nitrate of silver, found, as I had expected, that sulphate of silver was thrown down; and when the precipitated pyroxyline had been thoroughly dried, and had been made into collodion, no further deposit of sulphate of silver was obtained in a silver bath in which collodion made with this precipitated pyroxyline was alone used. I think this experiment tends to show that sulphate of silver, when found in a silver bath, is dissolved out of the collodion. In the course of experiments on this subject, I also found that nitrite of silver is a frequent cause of pinholes in the silver bath, and I have further remarked that it is far more copiously produced when plates prepared with a substratum are used in the bath, than when the plates used are simply cleaned. This we should naturally expect to be the case, as the nitrite of silver would tend to be freely produced where organic matter is brought into contact with nitrate of silver. In the course of these experiments, I have submitted the various commercial collodions, as well as those made by myself, to tests with regard to the production of nitrite and sulphate of silver in the bath, and I find that they vary extremely in their behaviour, one sample of collodion producing sulphate of silver alone in the bath, while the others produce sulphate and nitrite in various proportions, one of the best working collodions producing the nitrite in large quantities, and very little sulphate. If a nitrite is added to a collodion it increases the sensitiveness, and it may be that some makers add a nitrite to their collodion. I noticed at a former meeting what Mr. Blanchard said with regard to the colour given to negatives by the use of nitrate of uranium in the silver bath. It is, undoubtedly, the case that nitrate of uranium does modify the colour of the negative, but the result is more easily gained by the addition of a few grains of sulphate of uranium to the ordinary iron developer. It is certain that the quality of the negative is improved by the use of salts of uranium, and I believe that the excellent printing qualities of uranium dry plates are largely due to the use in the emulsion of nitrate of uranium."

Mr. FRANK GOODE, in response to the Chairman, said he had nothing to add to the discussion. He had been troubled with pinholes, and was so still. He was anxious to get rid of them, but he knew nothing about their cause or cure. He had at one time refrained from adding any acid to his bath, and he knew nothing of pinholes until he used nitric acid, to which, therefore, he attributed his trouble.

Mr. DUNMORE exhibited a plate covered with streaks, comets, and pinholes. It was produced in a bath which had been working well, and suddenly went wrong. He added some strong fresh solution, and all went well, and continued so. He was satisfied, he said, in answer to some questions, that the fault was not due to dust.

Mr. FRY said when a bath went wrong, he diluted with common water, which threw down excess of iodide, filtered, then added caustic potash and ammonia, boiled, made up the solution to the proper strength, set it in the sun for as long as possible; after this, sufficient nitric acid—very little—was added, and the bath generally worked well. When, after this treatment, the bath failed to work, it was placed with residues for reduction. Referring to M. Boissinas' plan of quick working, he said it partly depended on the use of a neutral bath.

Mr. S. DAVIS said the plan just described seemed, with one exception, to be Mr. Brookes' method described at the last meeting; but he worked it in an alkaline condition, whereas Mr. Fry, it seemed, added nitric acid.

Mr. F. C. ELIOT said he had two or three years ago described his method of using an alkaline bath, which he had constantly employed ever since, and he found none of the usual difficulties attending the nitrate bath. His bath was made alkaline by carbonate of silver, and a collodion sufficiently mature to supply all the acid required. When his bath showed any signs of being out of order, he added more carbonate of silver, and he did not believe that a bath saturated with carbonate of silver would dissolve iodide of silver. He was neither troubled with fog nor pinholes, and as he did a good deal of copying, the absence of fog was a matter of importance. He was careful to keep ammonium out of his collodion, using the iodide and bromide of cadmium and potassium.

CAPTAIN ABNEY, F.R.S., said he thought if a highly bromized collodion were used, it would be impossible to work with an alkaline bath. He believed that carbonate of silver was insoluble in nitrate of silver solution.

Mr. ELIOT used a full proportion of bromide, using the double bromide of cadmium and potassium.

Mr. BOOL, in answer to the Chairman, said he was quite familiar with the troubles under discussion, but he did not know of any remedy.

A MEMBER remarked that at the last meeting Mr. Brooks referred to the use of methylated spirits as a cause of pinholes. He had made a great deal of collodion, always using methylated spirits; but had no pinholes.

Mr. SPILLER, in closing the discussion by a brief summary of the experiences, stated that Mr. Eliot's experience strikingly corroborated that of Mr. Bashford, of Portobello, who pursued a very similar plan with great success. Some specimens he would hand round illustrated that Mr. Bashford had a high standard of working. He thought the evidence was strongly in favour of alkaline conditions, hitherto regarded as undesirable.

After some votes of thanks, CAPTAIN ABNEY read an abstract of a technical paper on the theory of the alkaline developer and the photographic image.

The proceedings then terminated, and the meeting was adjourned until June 12th.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE usual monthly meeting of this Society took place on Thursday, May 3rd, in the Rooms of the Society of Arts, Adelphi, the Rev. F. F. STATHAM, M.A., F.G.S., President, in the chair.

The minutes of the last meeting having been read and confirmed,

Mr. F. YORK read a paper on "Photographic Difficulties," during the reading of which he exhibited and described a rising front for the camera, showing contrivances for placing the lens at different heights.

The PRESIDENT said that Mr. York had done good service in relating his difficulties, showing that he would not be beaten by them. Photographers generally should be indebted to Mr. York for the great energy displayed, and the pains he had taken under

disadvantageous circumstances. With regard to his operations in sacred buildings, the results were of much higher importance than the simple commercial element, for they became of historic value—as, for instance, in the spread of our race in distant colonies, by these works they would have an opportunity of becoming acquainted with those grand buildings which were the pride and ornament of our own times.

Mr. HOWARD remarked that he also had had some experience in street photography, and had used a duplicate dark slide, which, having been put into the camera, was then taken out, and another substituted, holding the prepared plate, which then could be exposed without interruption. Also, that in steadying the camera upon smooth floors, some corks put upon the iron spikes of the stand would be found very useful. He narrated that being out in the country, his friend's camera was blown over, and openings made in the wood-work. They went into a village, and getting some putty, carefully filled up the cracks, and so got over that difficulty.

Mr. YORK observed that in using a rising front, great advantage arose from the introduction of the small symmetrical lenses, as they could, from being so small, be brought right up to the top of the camera; and stated that having, on one occasion, gone out without a dark slide, he simply wetted the inner face of the focussing glass, and laying the sensitized plate upon it, it remained fast whilst being exposed.

Mr. SPENCER also related that when taking a country view, it being just upon twelve o'clock, about five hundred children rushed out of school. He told them to sit in a row along the roadway on the opposite side, and they would all be taken in. As soon as this was done, he took his view, and the children were taken in also.

Mr. MAWDSLEY narrated that, finding himself on one occasion without the screw of his tripod stand, he pared a piece of hard wood, and forcing it into the worm, thereby made a thread which remained so perfect that he used it for a week afterwards.

A vote of thanks having been passed to Mr. York, Mr. BROOKS exhibited some specimens of emulsion transparencies, showing that he could produce great variety in the tone of colour.

Mr. YORK then stated that there were two subjects he was investigating which others might like to experiment with: one was the addition of acetic acid to the collodion, which remained the same colour as before. A neutral bath which gave fog, when tried with this acetic collodion, gave very satisfactory results—he had used one drop of acetic acid to one drachm of collodion. The other experiment was that mentioned by Mr. Henderson, namely, the use of alum instead of spirit in the developer. He (Mr. York) thought that possibly any sulphate—either of magnesia, soda, or potassium—might answer the same purpose.

The PRESIDENT remarked that at the present moment, there being a dearth of new discoveries, it was as well to return to subjects which, although old, might from the results of experience be made interesting; and alluding to Mr. Brooks' experiments with the magnet, said that although the matter was at this moment simply an experiment, it might turn out of great importance.

Mr. BROOKS observed that in carrying on further experiments with the magnet, he had been able to reduce the exposure from fifteen to two minutes, and also that in the remarks he had already made upon the subject, with a certain purpose in view, he did not state all the conditions under which he worked, and promised to be ready at the October meeting with another paper upon the same subject.

Mr. PEARSON said that the facts which might arise out of Mr. Brooks' experiments none may guess. Modern researches tended to show that light produces electricity. The proposition was that force or power was not destroyed. It had been shown that, taking the swing of a needle put in motion by electricity to be represented by 19, the force of the back swing was more—viz., 21. What, then, became of the force of light? In the human eye such was the power exercised by light that it became necessary for darkness and sleep to intervene, so as to recover its normal condition. Much, then, had to be investigated in connection with light as to its proper function in exciting electricity, so that the experiments of Mr. Brooks may help those who work in that field of enquiry.

Mr. B. J. EDWARDS having promised a paper on the "Nitrate Silver Bath" for the next meeting in June,

The proceedings terminated.

EDINBURGH PHOTOGRAPHIC SOCIETY.

An ordinary meeting of this Society was held in the Hall 6, St. Andrew's Square, on Wednesday evening, May 2nd. Mr. GEORGE A. PANTON, vice-president, in the chair, when the minutes of previous out-door and ordinary meetings were read, and the following gentlemen were admitted ordinary members:—Messrs. J. M. Skinner, J. Somerville, J. Reid, H. Millikan, J. Boyack, A. Bogie, J. McLaren, J. Ballastyns, and D. Reid.

The business of the evening was begun by the reading of a paper on "Ventilation of the Studio" (see page 219), by Mr. JOHN LAING, in the course of which he exhibited several working models of the apparatus recommended, the action of which was considered very satisfactory.

At the conclusion of the paper, Mr. BLANC, of Her Majesty's Board of Works, exhibited, in action, a model of a ventilator, the invention of Mr. Emerson, of America, which, he said, depended for its action on the same principle as that shown by Mr. Laing but was evidently much simpler in construction, and, according to his account, produced an up-draught with much less wind. He stated that these ventilators had been fitted up in a number of government offices, and were giving the utmost satisfaction even such large and fully occupied rooms as those of telegraph operators and letter sorters being kept comfortably cool and pure.

Mr. PANTON thought the members were much indebted to Mr. Laing for the clear exposition of Boyle's ventilator, and especially for the satisfactory experiments that he had shown. Throughout the paper the ventilation of the studio had been spoken of, while, in reality, it was rather the ventilation of the dark room that had been mainly referred to, the latter being in reality more necessary than the former, and, in most cases, more difficult to manage. While he fully appreciated the advantages of Boyle's patent, he thought the system which they had in use, and which he supposed was the invention of their predecessor, Mr. Moffat, was at once the simplest and most efficient he had seen. Immediately over one of the windows, and within a few inches of the roof, there is an opening made in the wall, about eighteen inches wide, and six inches in depth. This is covered by a board, hinged at the bottom, so arranged that it can be kept permanently open to any desired extent. One or two of the panes of the window were made to open, and the result was that the pure air rushed in through them, and the heated and impure air escaped by the opening above.

Dr. JOHN NICOL had no doubt that under certain conditions the ventilators both of Boyle and Emerson would be very useful. In theory they seemed to be faultless, and, judging from the action of the models, they would be found equally good in practice. In principle they were identical, but he rather inclined to give a preference to Emerson's, both because of its simplicity, and of its requiring a lighter current of air to bring it into action. They had, however, he thought, one defect in common—i.e., that they required a current of air to bring them into and keep them in action. So long as a pretty stiff breeze was blowing, it was not difficult, as a rule, to ventilate ordinary studios or dark rooms; but in such days of sweltering sunshin, when there was not sufficient wind to stir the leaves of the silvery beech, these ventilators would be of no use whatever, and those were just the days that ventilation was most required.

Mr. LAING replied that while Emerson's ventilator was certainly more simple than those by Boyle, they, in his opinion, were objectionable, as under certain circumstances there would certainly be a blow down or back draught; and, as regarded the system mentioned by Mr. Pringle, it would do tolerably well in fairly good weather, but in a stormy wind it would not do at all. He did not think there was much force in the objection urged by Dr. Nicol, as however quiet the day might seem on the level, there would always be a sufficient current on the house top to start and maintain the up draught.

Mr. TURNBULL exhibited what he claimed to be "an improved form of actinometer." It is of tin, about the size of an ordinary snuff box. On the lid, which is glass, is pasted a series of thicknesses of *papier minéral* arranged in the ordinary way. The sensitive paper is wound round a roller, and may be pulled out as required. So far as could be made out from the description, the principal novelty is the coating of the *papier minéral* with a film of collodion to protect it from being stained by the silver on the sensitive paper.

A number of really fine examples of the work done at the out-door meeting in Cadzow Forest were then shown by Messrs. ANNAN, of Glasgow, PANTON, Pringle, Mathison, Sinclair, &c., &c. Mr. ANNAN, who had wrought wet collodion, showed some brilliant pictures, groups both of men and cattle, and the cattle of both Messrs. Panton and Pringle, both from dry plates, were also first-rate.

Two motions, one by Mr. Sinclair, that medals be given under certain conditions for the best work of the season taken at the out-door meetings, and one by Dr. Nicol, that a medal be given for the best paper read before the Society, elicited a considerable amount of discussion, but both were ultimately withdrawn to enable the members to consider the subjects more fully.

The SECRETARY then reported that the Council had considered the letter from the Glasgow Photographic Association, requesting the co-operation of the Society in opposing the extension of Mr. Swan's patent for the manufacture of carbon tissue. The Council had fully considered the subject, and on the ground that the Society had invariably declined to entertain any question connected with the commercial aspects of photography, recommended that no action should be taken in the matter. After considerable discussion it was resolved to approve of the report, and the Corresponding Secretary was instructed to communicate the resolution to the Glasgow Photographic Association.

Dr. JOHN NICOL, in the name of Mr. Gutekunst, of Philadelphia, presented the Society with a large portrait of "Longfellow," of the same exquisite beauty as the smaller pictures shown by that artist at the late Exhibition. He also submitted for the inspection of the members a number of cabinet pictures, duplicates of those exhibited, and by Mr. Gutekunst's request, invited the fullest criticism of all. He reminded the members that there had been considerable diversity of opinion regarding the quantity of retouching on the exhibits of Mr. Gutekunst, and that a large number of the members thought that a mistake had been made in characterizing the pictures as so wrought upon as to place them out of competition with ordinary photographs. On the authority of Mr. Gutekunst himself, he stated that, with the exception of the lady with the hat and beads, the whole of the specimens shown were untouched prints from untouched negatives, and as most of them were duplicates of those in his case, the members might examine them for themselves. He, Dr. Nicol, had done so very carefully, and had no doubt that they were really what Mr. Gutekunst claimed for them.

Mr. TURNER was glad of the opportunity of expressing his opinion of the wonderfully beautiful pictures of Mr. Gutekunst. He had examined them particularly when they were in the exhibition, and was satisfied that there was very little retouching. In point of fact, they did not require it. They were printed with extreme care from almost perfect negatives, and the system of glazing gave a depth and transparency that had, by its rare beauty, misled those who considered such an effect due to excessive so-called modelling. He might add that this opinion had been fully expressed to one of the judges at the time of the Exhibition.

Mr. W. NIXON expressed himself much pleased with the pictures, and quite agreed with Mr. Turner in thinking that their extreme beauty had cast a doubt on the method of their production. A more careful examination, however, would make quite clear the fact that they were really nature's handiwork, as they possessed natural beauties that no retoucher could imitate, but that all would certainly mar.

Dr. HUNTER had never seen anything in photography at all approaching in beauty to those pictures of Gutekunst's. He was also very glad to see that the general opinion of the members was that they were photographs pure and simple, as it would be a stimulus to each to try and do work equally good. Good sometimes came out of evil, and for his own part he did not regret the little misunderstanding that had arisen, as it had probably led to the presentation of the noble head of Longfellow, that would be a lasting memorial of the exhibition, and the discussion would undoubtedly show that in the opinion of the meeting they were specimens of the highest class of pure photography. He proposed that the Secretary be instructed to convey to Mr. Gutekunst the best thanks of the Society for the very handsome gift that he had sent.

The proposal was unanimously agreed to, and votes of thanks having been given to Mr. Laing and Mr. Turnbull, the meeting adjourned.

BRISTOL AND WEST OF ENGLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE ordinary (and last indoor) monthly meeting of this Society was held at the usual place of meeting, the Museum, Queen's Road, Bristol, on Wednesday, 2nd inst., Dr. THOMPSON in the chair.

The minutes having been read and confirmed,

The SECRETARY read a long expostulation from the Glasgow Photographic Association, relative to the Bristol and West of England Association's reply to that Society on the subject of the Carbon Patent, and which caused some little merriment.

Colonel Biggs, of Bristol, was elected an ordinary member of the Association.

Dr. THOMPSON then read his paper on the "Collodio-Albumen Process" (in our next), which was listened to with marked interest, and which was illustrated with some very fine pictures.

Mr. BRIGHTMAN asked if Dr. Thompson had tried moistening the film prior to development with alcohol, to avoid blisters?

Dr. THOMPSON stated that he had suffered scarcely at all from the film blistering.

Mr. BRIGHTMAN congratulated him, remarking that the most of the workers of the process found blisters a great enemy.

Dr. THOMPSON stated that to be quite sure that no hypo was left in the prints, he often soaked them in a solution of salt, which accomplished that end.

Mr. DANIEL asked if he did not find that by so doing the tone of the pictures was interfered with.

Dr. THOMPSON said he had not found that to be the case, and stated that many of those before the meeting had been so treated, and which certainly showed no signs of being reduced in tone.

After some further discussion, the matter of the "June Out-door Meeting" was considered.

Mr. HOLY proposed that it should take place on the third Wednesday in June.

Mr. DANIEL seconded the proposition, which was carried.

The HON. SECRETARY stated that at the Council Meeting held a day or two previously, every other detail had been decided upon; the date simply being left open. He informed the meeting that Tyntern had been decided upon as the destination, and that ladies and friends would be welcome, so that the excursion may be made as enjoyable and social as possible.

On the motion of Mr. DAVY, seconded by Mr. ALDRIDGE, a hearty vote of thanks was accorded to Dr. Thompson for his most interesting paper.

The meeting was then adjourned.

Talk in the Studio.

COLOURED ENAMELS.—We have recently been favoured by Mr. Burton, of Nottingham, with a sight of some coloured ceramic photographs of great delicacy. Mr. Burton is a portrait painter of old standing, who has for some years devoted his attention to photography, and especially to the production of coloured enamels, bringing his old experience in painting to bear on this branch of the art. Many of his results are very fine.

SECOND-HAND APPARATUS.—Those of our readers contemplating the acquisition of new apparatus of any kind will be interested to know that Mr. Morley has just issued a new catalogue containing a very complete list of all kinds of photographic requisites.

NEW COMBINATION PROCESS.—Mr. Woodbury, inventor of the well-known photographic printing process, has just perfected an adaptation by which the Woodburytype process is combined with chromo-lithography. The colours are printed in tint, only as for an ordinary chromo-lithograph, over which, in place of a key-block, an impression is taken from a Woodbury plate, so that the colours seem as if reflected through the photograph. The effect is that of a delicately coloured photograph in which remarkably transparent pigments are employed. In the example before us, a cottage with thick foliage in the background, the minute accuracy and soft tones of the photograph suffer no obscurity, but are as clear and as well defined as in an ordinary sun picture.—*Bookseller.*

To Correspondents.

CLAIMANT.—So far as we know, the best solution for mounting enamelled prints, without injuring their glass, is glue dissolved with the aid of alcohol. We have published in the *News* and *Year-Books* many detailed descriptions of the operations, but we cannot with any certainty say which is the best. Each method requires practice, and that method which any one masters will be to him the best.

LEO asks which are the best dry plates. Our answer to **LEO** must, in tone, be similar to the answer which we have given to a correspondent above. When he has mastered a process, he will probably consider it the best. It is quite impossible to say which is best in itself. That which is most within the range of your experience will probably be to you best. Most dry plate workers at present are disposed to consider the emulsion processes best; but it is probable that to **LEO**, inexperienced in dry plate work, they would present many difficulties. A bath process will probably best answer his purpose, and probably none better than the coffee process, as described in our last *Year-Book*, which is simple, easy, certain, and excellent in result.

L. F.—Your colouring has good qualities; but a little more delicacy would probably answer better for photographic portraits. Your style of manipulating and your colour are bold; but a little more precision and delicacy would probably be more valuable commercially. There is no directory of photographers. Your only mode of addressing them is by advertising. If you wish to distribute samples of your work, advertise your willingness to forward specimens to applicants sending their addresses to you.

JAMES GORDON, JUN.—A dipper of silver wire will answer well. A silver dipper may be left in a neutral bath, but if the bath contain much nitric acid it would gradually act upon the dipper. We prefer glass. 2. There is no benefit, but often positive injury in daily filtering the nitrate bath. The use of a dipper which does not permit the plate to reach the bottom of the bath, and which consequently escapes any stored-up deposit, saves a great deal in filtering.

F. WHISTON.—The addition of alcohol to a developer serves no purpose beyond making it flow freely. It has no developing action whatever. We very rarely add alcohol to a developer, preferring to secure the satisfactory flowing by manipulation. The question as to whether six or eight ounces of water should be used is very unimportant, as the slight modification in the strength of the developer will merely make the process of development more or less quick. One or two drops of nitric acid per ounce may be added, and will make the development somewhat slower, and possibly add a little to the brilliancy of the image. 2. The proto-nitrate is not a very stable developer, unless kept carefully from the air by means of a good cork. The enlargements you mention are very good indeed.

G. G. L.—The proposal to purify soluble cotton by boiling it in water has not, so far as we know, been extensively carried out. We think it is certainly worthy trial. It has been found that in some samples a substance resembling glucose has been formed, which is soluble in water, and this, of course, may become dissolved out in the nitrate bath, which it will injure. This would be removed by boiling, and perfect freedom from acidity would be insured. 2. Pyroxyline is better kept in a jar or tin box with a loose cover. It is more liable to spontaneous change when kept carefully stoppered. Good photographic pyroxyline is not perfectly explosive. It flashes and burns rather than explodes. That made at high temperature yields a collodion which does not keep very well.

M. F.—Daguerreotypes and collodion positives were tinted with powder colours prepared on purpose. It is possible to tint paper prints so, but they must be kept under glass, as the colour would be easily removed.

F. M. Y.—When a service is volunteered, we are bound in courtesy to wait the convenience of the volunteer. We hope shortly to be able to publish the information required, as the promise has recently been renewed to us personally.

Several Correspondents in our next.

PHOTOGRAPHY IN AND OUT OF THE STUDIO.

DEVELOPMENT OF SCIENCE BY WAR.—AMATEUR PHOTOGRAPHERS.—ASTRONOMICAL PHOTOGRAPHS TAKEN FROM HIGH ALTITUDES.—PRODUCTION OF COLOURED PHOTOGRAPHS.

Development of Science by War.—If science aids war, war may fairly be credited with developing science. One of the most beautiful illustrations of what science can do under necessity was brought forth during the Franco-German war, and had Paris not been so closely invested by an enemy we should never have dreamt of the possibility of a *poste aérienne*. The manner in which the mails were regularly carried out of Paris by balloon, and a return-post established by the aid of micro-photography and homing pigeons, is so happy an illustration of applied science, that one might almost go so far as to think well of a war which developed so interesting a matter. The tiny photographic films, so thin and delicate that a pigeon could of itself carry no less than a hundred thousand despatches, is a wonder hard to believe in; and yet these winged messengers that entered Paris during the three months that the capital was cut off from the rest of the world were about the only bearers of news that could escape the vigilance of the ever watching Germans. No doubt many birds fell a prey to Teuton marksmen, and many more were frightened away from their destination by the noise of the bombardment around the city; but by repeating the messages forty or fifty times, and sending pigeon after pigeon with the films until the receipt was acknowledged by balloon post from Paris, the beleaguered garrison was kept informed of matters passing outside. Letters, or rather despatches, were received in the ordinary manner for transmission into Paris by pigeon (of course, bombardment permitting) from all countries, the charge made being one franc per word. The despatches were set up in bold type, many hundreds of them printed upon a sheet, and this sheet was then photographed in microscopic proportions. Prints upon a thin transparent film were obtained, and these, on arrival at Paris, were put into an enlarging apparatus, similar to a magic lantern. At first, clerks were employed to copy out the messages thus reflected upon the screen, but afterwards the enlarged characters were photographed, thus obviating all clerical labour. Such a system as this would never have been elaborated but for the war, and while the French thus availed themselves of photography to help them out of a difficulty, their foes, the Germans, were not blind to the importance of the art in warfare. Maps published by the French *Etat-Major*, showing every road and pathway throughout France, were secured and reproduced by the Germans by photo-lithography. These copies were distributed broadcast throughout the Teuton forces, and there was not even a captain who did not know the nature of the country his company was passing through. Again, for surveying purposes, the Germans employed the camera to a great extent. Before Strasburg, and subsequently before Paris, a photographing surveying staff were busily engaged in making observations and completing surveys with the aid of the camera, and the information thus secured was of infinite service in the reduction of those fortresses. In respect to the present war we shall no doubt hear of further applications of science. We know that certain Russian officers have for some time past been busy in elaborating a process of micro-photography in the field, for reproducing secret despatches and plans of microscopic size, and among the equipment attached to the Russian army is to be found cameras and other photographic requisites. On the other hand, too, we are aware that the Turks have for some time past been anxious to obtain the services of an experienced chemist to help them in many scientific matters, and, above all, in the manufac-

ture of gun-cotton, dynamite, and other explosives. Both belligerents are seemingly quite aware, therefore, of the assistance which science can afford them in the struggle upon which they are engaged, and we may be assured that, however much we may regret the war, results interesting to men of science will not be wanting.

Amateur Photographers.—We spoke last week of the trouble and expense to which amateurs at times put themselves to secure good pictures. When an Englishman takes up with a thing, he rarely does it by halves, whether it is work or play that is in question; and we were told the other day of a wealthy amateur, living not a hundred miles from South Wales, who affords a good example of what some people will do for the sake of an art they love and cherish. This gentleman, whose grand pictures are familiar to all who have visited recent exhibitions in London, in his desire to depict a scene beside the railway, and at some distance from his residence, made no difficulty about securing a special train for his purpose. Arrived at his destination, he found, to his great vexation, that his assistant had omitted to bring with him his lens, and there was no alternative but to wait until the engine had been despatched, and had brought back the missing instrument. Such an example of steadfastness of purpose and devotion to the art is perhaps without parallel in the history of photography.

Astronomical Photographs taken at High altitudes.—Professor Zeugner has been making some photo-astronomical observations in the Engadine, in Switzerland. His work has been undertaken mainly in connection with the sun and its corona, and he seems to have secured some novel and interesting results. With a telescope having a focus only four times as big as the aperture, he obtained a picture of the corona in which this is represented as a broad round ring of one, or at the most two inches. Around it is shown an outer and weaker ring. The plan of making observations at an altitude so great as the Engadine will no doubt be followed after Professor Zeugner has shown the advantage of choosing such a station. The Engadine, as many of our readers may know, is a Swiss valley on the confines of Italy and the Tyrol, and celebrated for its dry, clear air. Moreover, the valley is situated 6,000 feet above the level of the sea, and while affording a wonderful point of vantage to observers, it has the merit of being a very agreeable spot to live in. There can scarcely be a doubt, one would think, that astronomical photographs taken at this height (2,000 feet above Ben Nevis), and in a district far removed from moist plains and from the vapours of towns, are far more trustworthy and clearer than pictures taken under ordinary conditions. If we are to have photo-astronomical observatories, and to base astronomic calculations upon the results, it is necessary above all things that the latter should be as true and undistorted as possible, and for this reason we consider that Prof. Zeugner, in taking the step he has done, deserves the thanks of all astronomers and astronomical photographers. To all appearances he seems to have secured a better record of the corona than any yet obtained.

Production of Coloured Photographs.—The production of coloured photographs by the superposition of a transparent image upon a tinted basis seems to acquire favour with the public. Mr. Woodbury, it may be remembered, showed some pictures of this kind ten or a dozen years ago, and within the last year or two M. Leon Vidal has been busily working a similar process, except that the latter uses greasy ink, we believe, for printing a photographic image over the coloured block. Within the past few months Mr. Woodbury has again come forward with the process, a cottage scene coloured in this way having come under our notice; and in Germany, or rather Saxony, a similar process evidently has just been patented under the name of *Bent photographie*. With competition in three countries we should soon obtain perfection.

SUMMARY OF DISCUSSION ON THE SILVER BATH.

BY J. SPILLER, F.C.S.*

FIRST let me congratulate the Society upon the interest awakened by the discussion of the silver bath, which has extended over three meetings, and been spoken to by nearly twenty of our leading members, who have recorded their experiences as to the best methods to be followed either in its original preparation or subsequent renovation. There has been, on the whole, a remarkable coincidence of opinion respecting the merits of the barium nitrate process, which, instead of emanating with the suggestion of Mr. A. L. Henderson, as I had at first supposed, is of far older date, and was first described, in the year 1865, by Dr. Hermann Vogel, whose original communication to the PHOTOGRAPHIC NEWS has been reprinted in a recent number of that journal (March 23rd), and which, I am bound to say, goes so fully into the whole subject, that nothing seems to have since been added to complete the summary of Dr. Vogel's observations. Mr. York, however, showed at the last meeting of the Society some clear negatives which had been produced from a bath that had been intentionally saturated with sulphate of silver. I can only reconcile this apparent discrepancy of experience by assuming that the bath conditions were favourable to the retention of the sulphate of silver in solution, and that when this salt exists perfectly dissolved in a bath, and not in a state of super-saturation, the evils in question do not manifest themselves. Perhaps I may be allowed to explain what I mean by super-saturation. It is well known that we may dissolve sulphate of soda in boiling water far above the point at which it will dissolve in cold water. If the hot liquor be allowed to cool in a perfectly tranquil state, free from all agitation, the salt still remains in solution. If, however, a crystal be dropped into the containing vessel, crystallization at once commences till all above the normal amount of the sulphate that is held in solution by cold water is crystallised. Supposing a bath to be super-saturated with silver sulphate, the mere fact of immersing the plate may cause a deposit of crystals to be thrown down. It is not surprising that sulphate of silver is found in the bath, when account is taken of the manner in which the iodides are prepared. For instance, iodide of potassium is prepared from pearlsh, which naturally contains a quantity of sulphuric acid. We believe that "pinholes" arise either from the formation of crystalline deposits in the film, which afterwards get washed off during development, or they are due to points of inferior sensitiveness caused by the depositions of relatively non-actinic particles (as, for instance, of the yellow iodide of silver), which obscure the action of light at the time of exposure, but, being loosely adherent, become detached from the plate during the subsequent manipulations. A turbid bath will, of course, show them at once, and so likewise will a bath charged to super-saturation with any of the difficultly soluble salts of silver, amongst which the sulphate is one of the most likely to occur from impurities in the collodion or sensitising salts, as was hinted on a former occasion.

Since opening the discussion, and describing the bath deposits of sulphate and cyanide of silver which had been sent to me by the Autotype Company, I have been favoured with two fresh samples from Mr. Bashford, of Portobello, one of which was forwarded to me through the Editor of the PHOTOGRAPHIC NEWS. They both proved to consist almost entirely of the carbonate of silver, and yet were said to have been filtered out of baths showing a slight acid reaction, and of good working qualities. This observation lends support to the statement which Mr. Brooks made at the last meeting: for he found the addition of an alkaline carbonate most efficacious in the removal of impurities which appeared to be carried down, especially on boiling, and that a bath so treated permitted

of very rapid exposures—an advantage which Mr. Bashford particularly refers to in his letter. The last-named gentleman reminds me likewise of the practice of using carbonate of silver to prevent discolouration of the printing bath, and of its conferring good keeping qualities to the sensitised paper.

Mr. Sawyer offers a good suggestion in proposing to use a dilute solution of chloride of barium for washing the pyroxyline, which, if carried out, must effectually remove all traces of free sulphuric acid from the collodion, and probably add to its permanence. Mr. Spencer recommends the use of bromide and iodide of barium as offering an absolute guarantee against the introduction of sulphates with the sensitising salts. There remains only the nitrate of silver to be carefully watched for the presence of sulphate, and this can easily be tested before use by adding thereto a solution of barium nitrate, which at once shows the presence or absence of sulphate of silver, if pure water be used for dissolving the crystals.

A good deal of evidence was stated in favour of the cyanide process of renovating the bath, Mr. S. G. Payne, Mr. Burton, and some writers in the contemporary journals, affirming its advantages. Mr. Blanchard had not found much benefit in its use, but, like Mr. England, placed more reliance in using common water and then sunning the bath. Mr. W. Bedford is in the habit of selecting the largest crystals, of his own preparation, for making the silver bath, and thus avoids the necessity for introducing barium or other extraneous salts.

FURTHER NOTE ON ALKALINE DEVELOPMENT.

BY CAPTAIN ABNET, R.E., F.R.S.*

IN a communication to the *Philosophical Magazine*, and which was reprinted in last month's *Photographic Journal*, allusion was made to the reaction that took place in the developer when employing alkaline development, but not being at the time in a proper state for publication I did not think it advisable to give the entire details of the reaction.

Having been anxious to ascertain whether external oxygen had anything to do with the reduction of the bromide of silver, I thought it advisable to cause the alkaline developer to come in contact with the silver bromide in exhausted tubes, and then to note the result. I will briefly recapitulate the method of procedure.

Pyrogalllic acid was carefully dried, a known portion dissolved in water, and made to cover some well-washed silver bromide of known weight. In the other tube was placed a solution of potash of known strength and perfectly free from all carbonic anhydride and from chloride. The tubes were then connected with a Sprengel pump, and after an aqueous vapour vacuum was formed the alkali was caused to run over into the tube containing the bromide and the pyrogalllic acid. After allowing the liquids and solid to be in contact for a time—in some cases a fortnight—the tubes were broken, the liquid filtered off the residue, that latter examined for metallic silver, and the former carefully evaporated down to dryness in an atmosphere perfectly free from carbonic anhydride or other atmospheric impurity. It may be stated that in as many cases the liquid was made up to a known bulk, and a portion of it set aside for estimating quantitatively the amount of bromine present. It invariably was proved that within the limits of error of manipulation, the bromine in the solution always agreed with the amount of silver bromide reduced to the metallic state.

In the paper above alluded to it is stated that the whole of the bromine combines with the alkali to form a bromide, and that whilst a residue given by the brown solution when evaporated to dryness is totally insoluble in

* Read before the Photographic Society of Great Britain.

* The Photographic Journal.

absolute alcohol, the alkaline bromide can be dissolved out. In nearly every case this plan of treating the residue was resorted to. By so doing all excess of alkali was removed, leaving behind only that part which might be in combination with the organic salt. At first I was inclined to think that the pyrogalllic acid was absolutely decomposed into different compounds, amongst others, into carbonic anhydride, and that this was combined with the alkali.

I now find that such is not the case, for I find that acetic acid will not effect any change in the solution, no liberation of the carbonic anhydride taking place. If, however, nitric acid or sulphuric acid be added to it there is an immediate disengagement of the gas, and the brown colour of the liquid changes to a bright amber colour. It may be as well to state here that if this solution be evaporated to dryness we have a residue, part of which is soluble in alcohol, part in ether, and part insoluble in either. I have not thought it necessary to make an analysis of any of these, but the lesson learnt from it is that that compound, formed by developing, is readily split up into three others, together with carbonic anhydride. The next operation was the determining of the original organic residue. The combustion was undertaken in the usual manner. It was previously ascertained that each equivalent of pyrogalllic acid displaced four atoms of bromine. The following is a statement of results obtained directly on breaking the bulk:—

This is a compound in which five equivalents of oxygen are taken up. On exposure to the air, or after passing a current of oxygen through it, the new compound absorbs another five equivalents of oxygen, and we have—

The first compound formed is much darker than the latter, and something of the same phenomenon may be observed in dropping an alkaline solution in a moderately old solution of plain pyrogalllic acid, and the colour is first a deep brown, which, after mixing, the turbidity gives way to a more transparent and paler colour.

The examination was undertaken with solutions which answered to the strong alkaline developer. With weak solutions the reaction does not seem to be as complete; less silver is reduced proportionately to the amount of pyrogalllic acid employed. As far as I can tell at present, only one atom of hydrogen is displaced, and two equivalents of silver bromide reduced instead of four.

From the above it will be seen that alkaline development of an image is independent of external oxygen, and I may say further that the less external oxygen admitted the more complete is the reduction. If the developer be exposed to the air before application, as it is also whilst in the plate, another compound is partially formed which is less capable of reducing the silver bromide—in fact, acts as a retarder to the original solution. It may be for this reason that it is a safe plan, in developing a plate, to flow the developer over it, and then return it to the cup and allow the detail to appear. If the strong alkaline developer be allowed to remain on, the development is not so gentle, and there is a greater danger of veil. It must not be forgotten that the alkalinity of the pyrogalllic acid solution tends to make it absorb oxygen from external sources very rapidly, and that there is always the formation of the two compounds.

THE COLLODIO-ALBUMEN PROCESS.

BY G. S. THOMSON, M.D., F.M.S.*

THE collodio-albumen or Taupenot process, though one of the oldest of the dry methods, still maintains its place as

regards certainty and keeping qualities. Its other advantages are, that any slight error in exposure may be rectified in the development, and that the finished negative requires no coating of varnish, which of itself is no small recommendation. Its disadvantages are, the double coating, and the tendency to blistering of the film. The latter failing may be much, if not entirely, obviated by using new plates, or such as have not been repeatedly coated, and also by the employment of collodion yielding a powdery film. I find Kouch's "extra" answer well. The plates must of course be carefully cleaned, so as to possess a highly polished surface. I have never found it necessary to employ a preparatory coating of albumen, india-rubber, &c.

The plate is coated in the usual manner, and immersed in a thirty-five grain nitrate bath, the crystals being simply dissolved in distilled water; it is afterwards washed till the water ceases to show any turbidity, then drained on blotting-paper for three minutes, and the iodized albumen applied twice by flooding the surface of the plate placed over a shallow porcelain tray. It is then placed in a box on blotting-paper to ensure absence of dust, and allowed to dry. When dry, it must be heated over a spirit lamp till, by drawing the finger-nail round the edge, the albumen appears hard and horny; then allowed to cool, and immersed in the aceto-nitrate bath, consisting of—

Nitrate of silver	40 grains
Glacial acetic acid	40 minims
Water	1 ounce

It may remain here from two to five minutes. On removal wash as before, and when dry it is ready for exposure.

A great secret of success in this process is to give sufficient exposure. The plates I generally work with are ten by eight, with fourteen-inch lens focus. Under these conditions, and with half-inch stop, in sunshine I give eleven minutes.

I develop in a shallow glass tray, placing the plate face downwards, and supporting one side of it by a small strip of glass, so as to prevent its touching the bottom. By this means the developer remains clear to the end, and the surface of the negative is not stained.

I fix with hypo solution, to which I add adrop or two of acetic acid, just enough to destroy alkalinity and render it feebly acid, as with an alkaline solution blisters are very apt to arise. When dry, the albumen surface will be sufficiently hard to enable you to dispense with varnish.

The following is the formula I have used for the iodized albumen:—

Albumen	3 ounces
Aqua. dist....	1 ounce
Strong liquor ammonia	10 minims
Iodide of ammonium	10 grains
Bromide of potassium	10 "

Developer.

Cold saturated solution gallic acid	6½ ounces
Glacial acetic acid...	35 minims
Pyrogalllic acid ...	2½ grains
Solution of nitrate of silver (20 grains to ounce) ...	50 to 60 minims.

Do not add more of silver solution than is absolutely necessary.

THE CARBON PROCESSES.—A FEW HINTS TO LICENCEES.

BY LINDOP AND COOPER.*

Sensitizing.—At this season of the year one ounce of bichromate of potash to forty ounces of water is about the

* Read before the Bristol and West of England Amateur Photographic Association.

* *Anthony's Photographic Bulletin.*

proper strength. Immerse the tissue, the dark side upwards, and let remain (avoiding air-bubbles) until perfectly flat; then turn it over, face downwards, and let remain until the edges just begin to turn the other way; take it out in the way shown, and lay it face downwards on a clean piece of glass. Squeegee out all the excess of bichromate, and hang to dry in a perfectly dark room with the temperature at sixty or sixty-five degrees, and with a current of air through it, if possible.

The Tissue Becomes Brittle and cannot be Handled without Cracking.—To avoid this, as soon as the sensitized tissue is perfectly dry, place it in a large box as you fume albumen paper; place a pitcher of hot water at the bottom of the box; the steam arising will cause the tissue to become flaccid or limp, and will be as pliable as patent leather, and if placed in a tin box will remain so indefinitely. Never allow the tissue to remain exposed about the printing room, as it will surely become brittle again. After printing, mark them, and place in another tin box till developed.

Blisters Making their Appearance during Development.—If these be small they are caused by the water being too hot, especially at the commencement. It never should exceed ninety degrees at this stage. If they are larger they are more likely to be caused by small bubbles of air being imprisoned between the tissue and collodion by the squeegee, instead of being expelled by it, or from want of sufficient water on the plate while placing on the prints.

Tears and Dark Streaks Running down the Picture.—These are produced by removing the picture from the water during development and allowing it to remain in one position, so that the gelatine runs down in streaks and partially sets, and is not entirely re-dissolved by the time the development is complete.

To Retouch Spots on the Prints, or to give Fine Details in the Whites before Transferring.—Have by you a cup of hot water and a very fine camel's hair brush. Take a slip of plain tissue, give it a soak in the hot water, lay it on your palette and use it for colouring; warm your plate, use hot water with your brush, and you will soon be able to touch in the necessary parts so that you will not be able to perceive they were not printed. For increasing shadows on the print use powder No. 2 as explained.

Transferring and Mounting Full Gloss.—If at any time you find the transfer paper refusing to adhere to the print, immerse in a weak, hot solution of gelatine instead of warm water while transferring, instead of using starch or paste to mount full gloss. Take thin cardboard and immerse it in the gelatine solution used for transferring while still hot, and if anything a little stronger for mounting than transferring. When thoroughly saturated, mount it on the print when about half dry, rub it down well, put under a weight for half an hour, and let dry spontaneously. Or a surer way still is to make a good stiff paste with starch, strain it twice through cotton and squeezing it through with the hands; paste the dampened cardboard and prints with this, using a sponge instead of a brush to apply the starch; place under a weight for half an hour, and then dry.

Sundries.—Before placing the print on the glass to develop, examine the face of it, and by dashing on water you can remove any greasy appearance or dirt. See that the glass is thoroughly flooded with water. After squeezing the prints examine the face of them, and if you see glossy spots, be sure you have not had sufficient water on the glass.

Handle your tissue in a yellow light. Border all negatives, unless vignettes or medallions; the edges of these are already protected.

Try three or four on the photometer for your first experiment, and mark its own best number on every negative. By this means you need never lose a print. Keep the hands off the face of the tissue, as any finger mark will show.

Better to develop slow with water at ninety degrees, as if

too hot it produces harshness, and there is always a risk of cracking the tissue.

Use mineral powder No. 1 very sparingly until you get to thoroughly understand it. A little practice is all you require to retouch nicely.

In developing, if there be a very dense mass of shadow, which in any print would appear too heavy, this may readily be modified by taking a tuft of cotton-wool, soaking it in weak ammonia, and gently rubbing. You will be surprised how easily the mass yields to this treatment without destroying half tones. Pour a stream of cold water on the picture before putting it back into the water; this prevents the ammonia from adhering where you do not want it.

Fix with alum, and dry as slowly as you can conveniently. We place ours where they take about three hours to dry, without any danger of cracking. For placing on the transfer paper we think it best to let the plate lie tolerably level and float it with cold water. This prevents the introduction of air-bubbles better than dipping the plate in water.

We advise all our licencees to read the English journals. Carbon printing has taken such a hold in Britain that more than half the articles in the journals are devoted to carbon. All the best men, both professional and amateur, are contributors, and give just the information new workers in carbon require.

We hope soon to announce to our licencees the establishment of a firm in Toronto (which we have held for that purpose) to work in carbon exclusively, on the same principle as the Autotype Company in England, in enlarging and publishing for the trade and printing new hints and suggestions as their large practice and experience would give them; also giving licencees throughout the Dominion an opportunity of visiting and seeing the working of an exclusive carbon establishment. We also hope soon to start a Carbon Society, and publish a journal in its interest.

We have just bought from M. Lambert the remainder of the States, and as soon as we have disposed of them will devote ourselves to the advancement of carbon printing in Canada.

TREATMENT OF SILVER RESIDUES.

BY M. GEYMET.*

Of one hundred grammes of nitrate of silver consumed in the negative and positive process, only ten grammes are actually to be found in the negative and the print. The other ninety grammes remain in the washings, in the soda bath, and in the filters. How the silver may be recovered shall be described in the following lines.

1. The greatest amount of silver is to be recovered from the washings of the prints before toning. This water is poured into an earthenware pan, with any unserviceable silver baths and such liquids as may have been collected in the development tub—the waste iron and pyrogallie solutions, namely, which have been poured off the plates. In this earthenware pan are always kept some strips of copper, from which, from time to time, the grey silver powder which is deposited is removed. Into this same pan come other waste silver solutions and spent toning baths, but no liquids containing hyposulphite of soda in solution.

The pan should have a tap ten centimetres from the bottom. When the precipitate has settled completely, then the clear liquid above is allowed to run off. Every month the precipitate, which consists of almost pure silver, should be removed, and allowed to dry in a porcelain dish.

2. All papers which have come into contact with silver solutions—such as filters, spoilt sensitized papers, and unfixed prints—are collected and burnt to ashes.

* *Photographisches Archiv.*

3. The old fixing baths of hyposulphite of soda also contain much silver. These are collected in a tub or cask, which, like the pan, is fitted with a tap.

When the cask is about three-quarters full, there is poured into it a solution of *hepar sulphuris*, the same being stirred into the liquid by means of a wooden lath. The next day some of the liquid is taken out and examined in a test tube, a couple of drops of sulphide of hot potassium solution being added. If no precipitate results, it is a proof that there is enough sulphur in the cask already.

The experiment is repeated with a little more of the liquor, and this time a few drops of silver solution are added. As there still no precipitate, then it is a proof that there is too much sulphur, and more fixing bath must be added before proceeding further.

4. *The Melting of the Residues.*—The precipitates from the fixing baths are put upon a plate of sheet iron, and heated over an open fire. The other precipitates, resulting from washings, &c., are then mixed with the former, and thoroughly dried.

The dry precipitate is then mixed in the following manner:—

Dry precipitate	100 parts
Borax	50 "
Fused saltpetre	28 "

In fusing, the saltpetre is robbed of its water of crystallization. Crystallized saltpetre is put in a dish, and put upon a sharp fire. At first it fuses in its own water, then it dries, and a sharp fire will afterwards bring it into a state of fusion, and this fluid mass is poured out upon a stone. Saltpetre, after being fused in this way, is better than borax, the production of which is more difficult, although it is to be purchased in commerce.

With the above mixture an ordinary crucible is filled to the extent of two-thirds, and this is then put into the furnace. The muffle furnace employed for burning-in enamels answers the purpose admirably. Upon the lid of the crucible are laid a few pieces of charcoal, the furnace is filled with coke and charcoal around the crucible, and the crucible itself is filled up with the same materials. After the operation the crucible is broken, and there is found an ingot of perfectly pure silver which will dissolve in nitric acid, and from which nitrates of silver may be obtained.

To fuse the ash, there are mixed:—

Ash	100 parts
Dried carbonate of soda	80 "
Sand	25 to 60 parts

The crucible is filled as before, and the operation proceeded with in the ordinary manner.

MY PRACTICE.

IMPROVED METHODS OF WORKING—A TANK FOR WASHING PRINTS.

BY A. J. SHIPLEY.*

DURING the past two years I have operated in about twenty different galleries, stopping a few weeks in a place. Now, to make the thing practical, for that is just what we want, we will take the whole as one instance, and will call the operator or proprietor, John.

Well, John gets a fresh supply of chemicals, and drops us a card to come; he is ready to turn a new leaf. We drop in, take a survey of things generally, and go to work. We find the walls covered with receipts for collodion, developer, redeveloper, &c. Ah, John! too much formulae, one is all we undertake to work; that one was published in the *Bulletin* in September, 1874, except we modify it a little.

* Philadelphia Photographer.

We clean and scrub the dark-room. On the developing stand, in addition to the ordinary iron developer, we find pyrogallol and citric acid, bichloride of mercury, iodide, sulphuret of potass, and ammonia; all of which we have John carry down and out. Now we weigh out one ounce of fresh iron, which we dissolve in twenty-three ounces of water, add one ounce of acetic acid, and filter carefully. The bath stands at forty; we reduce it to thirty grains; collodion, after our old formula, except to every five ounces we add one ounce of plain collodion. Now all things are ready, and the first sitters are called in, and we proceed to the operating-room; here we find one of John's worst enemies, a white side-screen seven by nine feet square. We set it behind the background to get it out of the way quickly, and make a small frame two by four feet, cover one side with white, and the other with black muslin.

Our subject was a beautiful young lady, light hair and blue eyes. Now, to kill John at once, I turned the dark side of the screen to the sitter, and arranged the light so that an even flow crossed the face at an angle of about forty-five degrees. A plate was sensitized, the exposure given, and John rushed to the dark-room to see a (weak one as he supposed) negative that was sensitized in a weak bath with weak collodion, and to be developed with a weak developer. But when the developer flowed smoothly over the sleeping and invisible image, she awoke, and started into life, and kept coming till John shouted, "Stop, or she'll get away!" Now we had the first good negative John had ever seen taken.

Our next subject was a baby eight months old, and full of play, a fond mother, and two assistants; by some mishap, they all got into the operating-room. The baby does all right, but mother—well, the exposure stops at about three seconds. Again we proceed to the dark-room. This time setting the plate-holder aside, while I warmed the developer up to about 80°, also giving the plate a few minutes between the exposure and development, again we proceed to develop the image. Cupid came more quickly than John expected, but stopped before quite up to the standard; now I had at hand for the purpose a one-ounce (wide-mouth) bottle, in which I drained the plate; by so doing, I caught a few drops of free silver from the edge and back of the plate; with this I proceed to run the development a little further.

"Now what is to be done?" said John.

Never mind, John. We'll wash the little fellow; the negative, I mean. In this case the modulation was good, only lacking strength; to strengthen or intensify, as you please, we set it up in the window in a soft light before fixing; after exposing it to light one or two hours, it had the appearance of a negative intensified with permanganate. In this way I treat all my negatives that need any strengthening. By masking or protecting in various ways, any part of the negative may be brought up, gradation in backgrounds, one of a group, &c. In summer, be careful to set the collodion side next the window glass, else the flies will run over it with their dirty feet and speck the film.

Since we are not all able to buy a carbon process, owing to the enormous price, I will give my brethren a simple method of washing silver prints, thus making them sufficiently permanent to last, at least till able to buy something better if such it be. Make a tray eight inches deep, as large other ways as required; make a light frame that will just drop inside the tray; in each corner of the tray place a block of wood one inch square and three inches long, so as to raise the frame three inches from the bottom. Now get a net used for catching minnows, stretch over the frame, and fasten; for very large trays it will be necessary to have several large cords crossing underneath the net, to keep it from sagging too near the bottom.

The use of this apparatus will be too apparent to need further comment.

VIGNETTING CARBON PRINTS.

ONE of the common objections made by portraitists to the carbon process has been based on the difficulty—or impossibility, as it has been alleged—of vignetting a portrait printed in carbon. To vignette a print efficiently, it has been judged necessary that the process of printing could be watched, an operation not possible, of course, in printing in pigments. Mr. Greaves, of Halifax, has, however, demonstrated that vignetting can be managed in carbon printing most efficiently and expeditiously. We have been favoured from time to time with very charming carbon prints produced by Mr. Greaves, which, to being very fine examples of this mode of printing, have added the charm of artistic vignetting, the background tint merging into a grey margin, instead of the baldness of a white margin, the gradation or merging of background tints being in all cases most soft and satisfactory. We were informed by Mr. Greaves that he had a system of effecting this, and during the course of the past week he was good enough to demonstrate his method for our edification, having patented his method and the printing-frame by which it was effected.

We should explain at the outset that this method is devised with an especial view to rapid, as well as artistic working. The primary aid in the matter is a printing frame designed for printing nine card negatives or four cabinet negatives at once. The negatives to be printed together are, in the first instance, selected of similar printing density. These are arranged in the printing frame and fixed in definite position in an inner frame. A piece of sensitive tissue, carefully cut to a fixed size, corresponding accurately with the size of the inner frame, is then laid on the negatives, and the printing is commenced. But if the prints are to be vignettied, another frame, fitting outside, is placed on the glass of the printing frame. This frame is fitted with the vignetting arrangement, which consists of a series of pear-shaped apertures with bevelled edges, allowing the light to reach the print under the graduated edges. We should explain here that all the inner frames of the printing frame fit very accurately, and register quite perfectly with each other, their various apertures corresponding perfectly with each other and with the negatives underneath. In printing, the whole of the nine negatives may be of the same printing value, so that the indications of the actinometer serve for all; or they may be arranged in threes, each row of three having its specific printing value, in which case, three different actinometer indications must be taken, and when the row of quickest printers is done, it is covered up until the others are completed. When the printing and vignetting is completed, the frame of vignetting masks is

removed, and is replaced by a corresponding frame of tints. These consist of a pear-shaped mask of wood, corresponding with the pear-shaped opening in the vignetting masks, possessing bevelled edges like the latter. These masks fit accurately upon the places where last the apertures were. The wooden masks are fixed upon plates of ground glass, through which the margins of the prints are tinted; the time being, of course, regulated by the aid of the actinometer, to a depth of tint ascertained by experience.

The perfect fitting of all parts of the frame and its lightness make the work exceedingly rapid and easy. The production of nine perfect prints, printing, double vignetting, transferring, and development, was effected in little more than an hour after five o'clock on a somewhat dull May evening.

One singularly ingenious arrangement in this printing frame must not be overlooked. It will at once be seen that, although by selection and the use of *papier minérale*, nine negatives of similar printing density might be secured, it would not be easy to secure as many pieces of glass of precisely the same thickness. To compensate for the varying thicknesses of the glass, the upper half, or lid, of the printing frame is provided with an air-bag as cushion to secure elastic pressure, and this, of course, accommodates itself so as to give precisely the same pressure to every negative, thick or thin.

It will be seen that the whole arrangement is as conducive to rapid despatch as to accuracy, the nine carbon prints we saw produced being much more rapidly completed than as many silver prints could have been in the ordinary mode of working: and Mr. Greaves proposes his frame for rapid and perfect vignetting in silver printing, to which purpose, of course, it is adapted just as easily as to carbon printing. It is, as we have said, protected by patent: in what manner the patentee will make his invention available to the public he will doubtless announce in due time.

POROTYPE.

POROTYPE is, we learn from the *Photographisches Archiv*, a newly-devised process for copying copper-plate engravings, wood-cuts, and other designs of a like nature. It is based on the principle that porous paper which has been printed upon by fatty ink loses, wherever ink attaches, its porous character. An engraving upon paper is only porous when there is no ink, and will neither allow gas nor liquid to penetrate wherever the black ink appears. A gas which acts upon a certain chemical agent, and either bleaches or discolours it, is permitted to penetrate a copper-plate engraving or wood-cut, where possible, and coming into contact, as it permeates, with paper which has been suitably prepared, brings about a reaction—that is to say, wherever the gas has found means to penetrate, the colour of the prepared paper alters, and a copy of the engraving is in this way produced.

In the process, therefore, four papers are necessary one, which is capable of generating gas, and which is soaked with hyposulphite of soda; a second, or sensitive paper, which is, in fact, paper treated, first of all, with extract of nut-galls, and afterwards with sulphate of iron solution (ink paper); thirdly, filter paper; and fourthly, oiled paper.

The copying of the engraving may be effected in the leaves of a book under pressure. The engraving is put upon the sensitive paper, and upon the engraving is laid the generating paper. Over these is laid a sheet of filter paper which has been previously impregnated in dilute sulphuric acid; then a sheet of plain filter paper; and lastly, the oiled paper. The whole is pressed together for ten minutes, when the copy ought to be finished.

A report upon the process by Professor Büttger is not very favourable to it.

THE PARIS DRY PLATE COMPETITION.

M. CHARDON'S PROCESS.

It will be remembered that last year the French Photographic Society instituted a competition among dry plate workers, and a prize of five hundred francs was offered by the Minister of Public Instruction, to be awarded to the author of the best process. MM. Ferrier and Davanne were charged by the Society to report upon the processes submitted, and according to the judgment of these gentlemen, which has just been printed, there appears to have been only one *bona fide* competitor. This gentleman, M. Chardon, has been awarded the prize. We extract from the report the details of M. Chardon's process.

The process of M. Chardon is distinguished by the preparation of a dry emulsion formed exclusively of bromide of silver enclosed in pyroxyline, by the absence of any preservative in the dry emulsion, by the great porosity of the film, by the addition to the alkaline developer of an intensifying liquid, which is added as soon as the image begins to show itself.

We will now proceed to the preparation of the products and the manipulations, emphasising the circumstance that in all delicate processes of this nature the very best materials only must be employed.

The pyroxyline employed must be of a horny, pulverulent nature, such as becomes dusty on handling. The cotton precipitated by boiling water seems particularly suitable for the process. The quantity varies with the solubility of the mixture of ether and alcohol. Under ordinary circumstances, the quantity of pyroxyline should be equal to the quantity of soluble bromide added to the collodion. If the pyroxyline is excessively soluble, larger proportions of it must be added. The bromides being always of a variable character so far as purity and dryness is concerned, it is necessary that they should be subjected to a preliminary operation.

Bromide of cadmium contains from twenty-five to thirty per cent. of water; you commence by drying slowly over a mild fire, agitating the while, until after a sort of fused paste has been formed you get the preparation in the form of a dry powder. Bromide of ammonium is dried in the same way, but with less heat; these are then weighed with accuracy in quantities in the proportion of their chemical equivalents, the equivalent of bromide of cadmium being 136, and that of bromide of ammonium 97. Thus, for example, 13.60 grammes of the first, 9.70 grammes are taken to produce 23.30 grammes of the double salt; and if one does not want to enter into calculations, you may simply double or treble, &c., these proportions.

The two salts are mixed, and dissolved in a small quantity of water; the solution is filtered, evaporated over a mild fire until it is perfectly dried, when it is put into a stoppered bottle, ready for use.

The bromide of zinc is, on the other hand, dissolved in absolute alcohol to separate the little oxide of zinc which is almost always mixed with the salt; the solution is filtered, evaporated upon a water-bath, and then heated over a fire until complete desiccation is reached; this very hygrometric product should always be weighed the moment it is dried: the equivalent of pure bromide of zinc is 112.

When these products have been properly prepared, the collodion is composed as under:

Alcohol	200 cub. cents.
Double bromide	6 grammes
Bromide of zinc	6 "
Pyroxyline	6 "
(Or more according to its solubility.)				
Ether	400 cub. cents.

It is well to prepare in advance a certain quantity of this collodion, which should be left to settle in order to acquire a perfectly limpid character. It cannot be filtered,

because the evaporation will produce changes in the proportions of which it would be difficult to keep count. For the same reason it is desirable to keep the bottle containing it hermetically sealed.

After standing sufficiently to clarify, you proceed to the process of sensitizing, and from this moment all the operations ought theoretically to be carried on in the dark, although practically an orange-yellow light, as feeble as possible, is employed. It is well not to sensitize too large a volume of collodion at a time; a hundred or two hundred cubic centimetres is enough to operate upon at one time. You commence by powdering very finely some pure fused nitrate of silver, and preparing separately the following:

Collodion	100 cub. cents.
Powdered nitrate of silver	3.10 grammes
Alcohol	30 cub. cents.

The nitrate of silver, accurately weighed in a balance that turns accurately to one centigramme, is put into a small flask, and to it is added one cubic centimetre of distilled water. The flask is then warmed until the silver is dissolved; half of the alcohol is added, and the flask again heated, and then the clear liquid is poured by degrees into the bromized collodion, taking care to agitate continually. Additions of alcohol are renewed in the flask, and then added to the collodion until all the nitrate of silver has been exhausted. The last portion of the alcohol serves to rinse out the flask. The bottle of emulsion is shaken vigorously, and then allowed to stand in the dark for thirty-six hours, being shaken from time to time.

Whatever the care taken, whether in the measurements or in the weighings, it is impossible to secure theoretical accuracy; but as the quantities here set down are quite precise enough, it is necessary to discover whether the conditions are favourable—that is to say, whether there is an excess of silver, and whether this excess is very considerable.

After thirty-six hours it may be presumed that reactions have come to an end. A small quantity of distilled water is therefore taken in a test tube (say ten to fifteen centimetres), and in the dark you pour into it about two cubic centimetres of the collodion to be tested. The mixture is shaken, then filtered through good white filter paper (Berzelius paper), the liquid being passed and re-passed through the filter until perfectly clear. To a portion of the liquid is added two or three drops of salt water, which should produce very apparent turbidity, a curd-like precipitate indicating a rather large proportion of silver. From the moment when the process of filtration begins you may operate in full daylight. It is only the bottle containing the emulsion which must always be preserved with the greatest care in the dark.

If the salt water does not produce any turbidity, you take, in another well-cleaned test tube, a further quantity of the liquid, and add to it a small quantity of a solution of silver. If turbidity or precipitate is formed, it is a proof that the collodion contains soluble bromide. It is necessary in that case to add to the collodion a further quantity of alcoholic solution of nitrate of silver, although it is always inadvisable to make this addition a second time; better is it to have an excess, rather than a lack, of silver.

If the collodion is proved to possess an excess of silver, it must be saturated, which is done by adding to every hundred parts of emulsion two to three parts of chloride of cobalt collodion, made up according to the undermentioned proportions:—

Alcohol	80 cub. cents.
Chloride of cobalt	10 "
Pyroxyline	2 grammes
Rectified sulphuric ether	120 cub. cents.

(To be continued.)

THE CARBON PROCESS OF TO DAY.

BY E. BATHO.*

SUPPOSING a piece to be sensitized with the precautions as indicated, the time occupied in its drying will permit of more attention being given to the negative, or rather the preparation thereof, than usually falls to its lot. With the utmost care, it seems impossible to produce a series of negatives that will print in equal times. Every printer in silver knows this, and accordingly humours his negative. One he will print in the sun, another in the shade, and carry out the thousand and one little niceties that serve to distinguish the mechanical printer who estimates his ability by the number of prints produced, and him who judges by beauty of result. In the matter of pigment printing a great power is denied—viz., that of watching the picture grow, as it were, into a thing of life, and thus use the light as the artist his brush. The only thing that appears to me to compensate for this loss is such modification of the negatives as will bring them into closer relationship in reference to density, so as to reduce as much as possible the chances of error in exposure during the subsequent printing, especially as its estimation must require more skill, seeing that in the case of silver printing the power of sight serves to correct the errors of judgment. Hence, so far as possible, bring all your negatives into such a state as to print in about equal time. To do this, the backing of the negative with tracing-paper seems an admirable way, and certainly is effective. Several thicknesses are sometimes required if a rather dense negative be chosen as the standard. Each must select this for himself; but for certainty of result, some method having this equalization of the printing quality of the negative seems to me imperative.

The actinometer next claims notice. The ordinary instrument is far from being what is wanted. Speaking personally, I have not yet found any two individuals to each register a tint, and, upon comparison, for them to be found of the same tone. This, however, does not interfere with its usefulness when it is always used by the same person, and estimated in the same light. Yet its want of sensibility is a great drawback. Still, this may be given to it by selecting a light tint as the standard for comparison; but the constant attention required would prove so irksome as to ensure neglect. The actinometer as used by Mons. Lambert is a much better instrument, and with a little modification answers every requirement, such change being a more sensitive scale. The intervals between the tints are too great for ordinary use. Where the more sensitive scale is employed, the eye gives an alarm in sufficient time to prevent any serious evil from over or under printing.

From the nature of my heading, it seems but natural that I should go on to describe every detail involved in the carbon process of to-day. Such, however, would be a waste of space, seeing that we have a manual that for clearness of style is equal to all instructions given in such form. This must be an excuse for what might otherwise appear unaccountable. My efforts will be directed to such details as I found in practice to aid me in overcoming difficulties in pigment printing.

The printing of the tissue can on most unimpeachable authority be left to mere boys, *provided everything is so left as not to need any more attention than you may expect of boys.*

We now come to the preparation of the plate which is to form the support upon which the picture is to be developed. How this is done when it is intended to form the permanent basis need not occupy our attention. When used simply as a temporary support, conditions must be maintained that may be stated as follows:—Some material must be placed between the gelatinous film and the support that has enough adhesive power to hold the picture to the glass during the operations of development, &c.,

but not sufficient to cause permanent attachment. Simple though this seems, yet it is here where I think many, if not most, of the early failures were made. Beeswax is the material generally employed. The methods of using have been various, but a solution of the wax in benzole when rightly employed leaves nothing to be desired. There is one danger that must be carefully guarded against, and that is the removal of the fatty layer during the subsequent coating thereof with collodion; but little notice seems to have been called to this, yet when it is stated that beeswax is soluble in ether, and partially so in alcohol, but little surprise will be shown at the statement that the fatty layer can be, and sometimes is, removed in the operation of collodionizing. The remedy for this is twofold: first, a saturation of the collodion with the wax (a means, by the way, of avoiding the trouble of waxing), or an extremely alcoholic collodion. The latter of these methods I prefer. Attention to this will ensure an absence of all sticking tendencies.

The mounting of the exposed tissue on the prepared plate is an operation requiring some amount of skill, yet, withal, extremely simple, the perfect exclusion of air being an absolute necessity. The temperature of the developing bath has been stated with figures somewhat varying: with recommendations to commence development with hot water, and end with cool, again with cool and end with hot, to use cool entirely or to use hot entirely, one is apt to get confused. A simple and reasonable rule is as follows: *Develop at a temperature 5° Fahr. higher than that temperature found to dissolve the unsensitized tissue.* An observance of this ensures the maximum half-tone, along with purity in the high-lights.

(To be continued.)

GERMAN CORRESPONDENCE.

VIOLET LIGHT IN ATELIER—INTENSIFIER WITH SALT OF LEAD—PHOTOGRAPHY IN THE HUMAN EYE.

BY DR. VOGEL.*

I SEE there is again some sensation about the new invention of Mr. Scotellari of applying violet lights in the atelier. It is always good when some new idea keeps photographers in agitation; but it is a pity when such a new idea is nonsense. Mr. Gaffield has spoken about this matter in a very plain and unambiguous manner, and has irrefutably shown by his experiences that the transmission of beams through a violet glass is of less chemical effect than through a white one. But there can be made the objection that Mr. Scotellari uses no violet glass, but a violet varnish, and that is in fact a great difference. The ordinary violet glasses are strongly coloured with manganese, which produces in the glass no colour of a clear spectrum-violet, but a mixture of blue and red. Through those glasses but very little of the clear violet of the spectrum is transmitted. The result with Scotellari's varnish may possibly be quite different. I have had no chance yet to examine the same spectroscopically; but probably it contains some kind of aniline violet—perhaps methyl violet, which in fact transmits the chemically effective light a great deal better than violet glass. According to that, Mr. Gaffield is perfectly right when he says it is impossible "that cutting off a portion of chemical rays by violet screens can shorten exposure and give more rapid chemical action." And he is so much the more right, as the most chemically effective light is not the violet, but the indigo blue at the line Z of the solar spectrum. I have made several hundred of spectral photographs, and am making them yet, but in all these works with bromo-iodide of silver, it was to be noticed that indigo blue very near Z had a stronger effect than violet. And now at least this matter has been examined by the committee of the Photographic Society at Paris, and one point is fixed, namely,

* Continued from page 222.

* Philadelphia Photographer.

that no shortening of the time of exposure under violet light can be noticed.

The committee worked in an atelier where half of the glass wall was covered with the violet lac, and has found out that the exposure on the side of the atelier with violet glass required just as long a time as on the side with white glass. And, after all, it seems as if violet light would be just as good as white light.

But the matter can be explained in the following way: Suppose we have an atelier without any curtains, one half with white, the other with violet glass. A person sitting in the violet part turns the face towards the white part, and receives, of course, a white front-light; but the person sitting in the white part turning the face to the violet part, the latter receives a violet front-light.

In the first case we have violet side and top light and white front-light; in the second case, white side and top-light, and violet front-light; and it can be easily seen that the result, under these circumstances, would be the same.

Some time ago I had a chance to report about the lead strengthening of Eder and Toth. In this method now some modifications are made which prove excellent for strengthening negatives of drawings where a thick cover is required. The plates should not be over-exposed, in order to have the lines as clear as possible, and developed, after which they are to be fixed immediately, and washed thoroughly. As a test of good washing we may let fall a few drops from the plate into a small quantity of a very weak solution of iodine tincture in water. When the solution does not discolour, the plate is clean. Then we have to lay the plate for about ten to fifteen minutes in a filtrated solution of four parts of nitrate of lead and six parts of red prussiate of potash in one hundred parts water. It turns therein to yellow-white, and consists now of ferrocyan-lead and ferrocyan-silver. These plates ought to be washed very clean, and may then be treated in several ways: 1. By pouring over them a solution of one part bichromate of potash in ten parts water. This solution we have to mix with one-quarter of its volume of ammonia. By this the white negative is changed into a yellow chrome-lead picture. Such plate seems to be very thin, but covers very well. We receive yet a better cover when we (2) add to the solution of bichromate of potash the same quantity of ammonia or a little more. Then the plate changes into chrome-red, and this cover will answer in most cases. But if we wish an entirely untransparent cover, we have to pour over the plate, after placing it in the lead solution and washing, sulphuret of ammonium, which will turn it entirely black and opaque. Strengthening by the latter is only necessary for photolithography. This strengthening is made use half of by my scholars and by myself, since the last year, with the very best success. But it is necessary that the collodion and silver bath work very clear, otherwise veiling will be produced. In order to receive very clean plates I usually add to eighty c.c. collodion one drop of nitric acid. Also it is important to wash the plates thoroughly after fixing them and taking them out of the lead bath.

Since some weeks the topics of conversation in photographic and literary circles are about some great discoveries in physiology. Parisian friseurs and coiffeurs are usually recommending their oil for the growth of hair with the following phrase: A discovery of immense importance has been made. The natural laws of the growth of the hair are revealed. And then follows the praising of the new hair-oil. But I have not to advertise a hair-oil, neither a photographic receipt, but I have to state only the fact that the natural laws of sight are discovered, and that after the discoveries of Boll and Kühne the sight of the eye is a photographic process. We have, in fact, a light, sensitive cover on the retina of our eye, the sight-purple. On this there occurs a photographic picture while looking at something, and, therefore, every person is a photographer, though no one knew anything about it.

Boll has proved that there is existing on the retina of the eye of each animal, of course of man too, a purple substance, which in the light soon disappears, but always regenerates, that is, renews itself by the process of light. In a yellow light the sight-purple is not changing, and Boll could on that account, in a yellow sodium light, better examine the relations of the same. He says: "We must imagine that while looking at something always some sight-purple is destroyed, and by some process renewed again, about which Boll has expressed his suppositions already."

Mr. Kühne succeeded in discovering that the reproduction of this coloured substance was the result of the contact of the retina with its natural underlayer. Among other proofs of this fact, he succeeded also in partly taking off the retina, bleaching it under the effect of the rays of light, and then, after carefully putting the bleached retina on its natural underlayer, saw the purple appear again after some minutes. Mr. Kühne succeeded repeatedly in this regeneration of the sight-purple, but it occurs only in a live condition. If the underlayer of the retina lost its life, the bleached purple does not colour again.

After these facts it was to be expected that we would succeed in the fixation of the little pictures which by exterior objects are produced on the retina of the eye. The first positive success in this direction Mr. Kühne had on January 15th. Afterwards he succeeded with a whole series of favourable results in photographic trials, of which we will describe only one.

A rabbit, after being excluded from the light for about five minutes, was placed in live condition towards the only window of a room. The distance between the cornea and the illuminated first row of window-glasses was 1.75 metre. After an exposure of three minutes towards the cloudy sky, the rabbit was decapitated, the eye taken out immediately, opened in a yellow light, and put in a solution of alum; and two minutes afterwards the other eye in the head was exposed to the window and treated in the same manner as the first one. Upon examination of the pictured eye-bottom no impression could be seen on the fine rose-coloured, moist, and shiny-looking surface. But after remaining in the alum solution for twenty-four hours, the result was astonishing. The back of the retina of that eye which was sensitized in live condition showed only a faintly visible impression, but that of the eye exposed while dying, gave the complete picture of the window, with six square panels and one glass cut round at the top, white on red background, with sharp red cross-work of the window. The picture showed downwards some perspective shortening of the upper row of the window-glasses and the arch of the window.

Plainer yet was the trial with the head of a just decapitated rabbit which was kept with one eye directed upwards to the top-light of the laboratory for about ten minutes, after which the head was turned and the other eye exposed the same length of time. After remaining for twenty-four hours in a five per cent. solution of alum, there were to be seen the most excellent pictures of the framing of the top-light on the exterior side of the retina of both eyes.

This discovery is wonderful enough; but for photography one thing is of special importance, namely, that the sight-purple is evidently a substance of astonishing sensitiveness. Our eye can distinguish very easily all details in the darkest corner of a room in a moment, while in photography it takes an exposure of hours to receive a poor picture.

The discovery of the sight-purple will lead perhaps to some other discoveries of substances very sensitive to light, which may be of great advantage to photography.

ALKALINE SILVER BATH.

THE Editor of the Photographic Society's Journal says:—

"In the late discussion on the silver bath, several members insisted on the alkalinity of the bath being of great importance, in order to secure rapidity, and from what fell from

them, the practice seems to be to use highly-coloured collodion; in other words, collodion in which iodine had been liberated. Where there is free iodine present, its contact with nitrate of silver must cause the formation of iodate of silver with a liberation of nitric acid, and it is presumable that this liberation of nitric acid in the film itself is more effectual in preventing fog than if the bath solution itself be acid. We have never met with a case in which bromized collodion shows a liberation of bromine; though such a liberation might take place unperceived, since with alcohol bromine forms bromal, a colourless compound, which it is as well to keep at a minimum if sensitiveness is a desideratum. Were bromal present in a collodion, there is much doubt if nitric acid would be liberated from nitrate of silver. Hence, with a bromized collodion the acid necessary to secure freedom from veil should be in the bath solution. When a large quantity of bromide is used in comparison to that usually adopted, though there is but little chance of liberation of bromine, and though there may be free iodine in the collodion, it may happen that this will not liberate sufficient nitric acid to secure cleanness in working, in which case also it would be necessary to use acid in the bath solution.

Correspondence.

STRONG AMMONIA DEVELOPER.

Sir,—This developer, now so much used in dry-plate photography, is directed to be made by dissolving one drachm of carbonate of ammonia, in powder, in one ounce of hot water, a process which involves—first, the use of scales and weights; second, of a pestle and mortar for pulverisation; and, third, the employment of hot water, and consequent injury to the resulting solution.

May I suggest a simple plan which I am sure dry-plate workers will appreciate (especially those who are away from home) of dispensing with all these difficulties?—viz., by adopting my own plan, which is simplicity itself.

Take a bottle of any size, and half fill it with fragments of carbonate of ammonia; fill the bottle with common water, cork tightly, and shake occasionally. When developer is wanted, take any quantity of this saturated solution and dilute with half its bulk of water, and as one ounce of water will dissolve about ninety grains of ammonia, this solution will, of course, contain one drachm to the ounce.

I fear this simple suggestion will provoke a smile from your scientific readers, but from its very simplicity it may not have been thought of by many.—Yours sincerely,

PHOTO-CHEMISTS.

PHOTOGRAPHY IN MELBOURNE.

Sir,—Though not a subscriber, I have for years been a constant reader of your journal, so that I trust you will allow me a little space to correct a communication you published from Mr. Cherrill some two months since. He speaks of Melbourne and its photographers—the want of art culture and taste so noticeable in their compositions. He says that the prices are low, and the pictures not good, and that he is of opinion there is room for a really good artist. Now, to come to facts, Melbourne is over-run with photographers, who find it as much as they can do to make ends meet. Their names are as follows:—B. W. Burman, T. Noble, A. Davis, C. Soden, J. Beaumont, W. Davis, C. Perry, G. Hewitt, J. B. H. M. Atrey, G. Shurt, Johnstone, O'Shannessy and Co., T. Chuck, F. Hasler, Benson and Stevenson, W. Sharp, J. Hilding, R. Wren, T. Bardwell, F. C. Burman, American Company, Batchelder and Co., Foster and Martin, C. Tanner, C. Nettleton, E. Pollard, Paterson Brothers, A. Goulter, J. K. Brennan, S. Nathan, D. Wood, McAlpine, Van Houten, McDonald, Bear, Hall, and Steward and Co.—in all, thirty-seven.

You will, I am sure, agree with me that Melbourne is at present amply supplied with photographers.

My only object in writing is to prevent any man coming out here thinking to find an opening, and, after crossing the ocean, discovering he is the victim: a too elegantly worded letter.

As I am totally unknown to you, doubtless you will feel cautious about accepting my statement; but if you communicate with Mr. Mayall, of London or Brighton, I am certain he will corroborate my letter in every particular. Thinking there was an opening, he came out here, and invested a large sum of money in the erection and furnishing of a studio, but did not find out until it was too late that Melbourne was overstocked with portrait takers. He returned to England, last year, much poorer for his trip.

It is a great pity that Mr. Cherrill did not personally ascertain the truthfulness of the information offered him before committing it to paper, thereby, perhaps, inducing some adventurous person to emigrate to this Colony.

The price of cartes is seven shillings and sixpence per dozen. One house charges ten shillings and sixpence; but the ruling price is seven shillings and sixpence. The pictures are very fair, and one house, in particular, turns out pictures equal to anything I have seen from London and Berlin, and they only charge seven shillings and sixpence.

Mr. Cherrill then goes on to state that operators receive from four to six guineas weekly, and in some cases eight guineas. It is pretty clear that he has been made the dupe of some practical joker, as there is not a single operator getting more than four pounds, the salaries running from two pounds to three pounds ten shillings. Out of the thirty-seven photographers in business, thirty-three employ no operator, only an assistant being required in the dark-room, so the remaining four firms cannot find sufficient employment for the number awaiting situations.

Mr. Cherrill's communication is so temptingly worded that a young man might be induced to venture so far from home in the hope of securing a permanent and lucrative billet; but there are at present several talented young men positively begging for a situation.—Apologising for the length of my note, I remain, yours truly, FINE ATKINSON.

3, Denials Terrace, Church Street, Richmond, Melbourne.

Proceedings of Societies.

EDINBURGH PHOTOGRAPHIC SOCIETY.

The second out-door meeting of the season was held on Thursday, the 10th inst., the scene of operation being Bothwell Castle.

Assembling at the West End station at 8.30, the members took train to Hamilton, where conveyances were waiting in which the drive to Bothwell was accomplished. The weather for some days previous had been dull and disagreeable, but the party were hopeful that a slight breaking up of the clouds indicated an improved state of matters as probable. In this they were not disappointed, as by the time the Castle was reached the sun had appeared with all his cheering influence on the would-be landscape photographers. The day, however, was not by any means favourable for photography, as during the whole course the wind blew a pretty stiff gale, the result of which was not only the limiting of the subjects to such as were least affected by it, but, in more than one case, the over-turning and seriously injuring of the cameras.

Bothwell Castle stands on a beautiful green bank, high above the Clyde, and is considered one of the most magnificent ruins of its kind in the country. It measures some two hundred and thirty-four feet along the summit of the bank, terminating at each end in a lofty massive tower with walls over fifteen feet in thickness. The date of its foundation is lost in the obscurity of the past, but it existed as a great baronial stronghold in the days of Wallace and Bruce, and was for some time inhabited by Edward III. of England.

Members attending such out-door meetings, especially those who work large plates, know how desirable it is that the party should include a few friends without cameras ready to lend a hand in carrying the apparatus from place to place. That it is not

always well to trust in such aid, however, was made manifest by an incident that occurred at an early period of the day, and which rather damped the spirit—for a time, at least—of one of the party. As the members assembled at the Caledonian Station, the traps were disposed of in various compartments, there not being a carriage in the train to hold all present, and when the necessary change was made at Hollytown each seized on as much as he could carry, altogether irrespective of ownership. Trusting to the united action to have transferred everything to the train on the Hamilton Branch, they went on their way rejoicing till they arrived in that town; but on taking stock, after being seated in the conveyances, the unpleasant discovery was made that one tripod was missing. A hurried run back to the train resulted in the information that the truant tripod would by that time be far on its road to Greenock, and could not certainly be available for that day. But photographers, perhaps more than any other class of the community, have a friendly fellow-feeling for each other in case of difficulty, and some of the party, remembering that Mr. Birrell, the inventor of the oxyhydrogen apparatus, lived in Hamilton, suggested an application to him and he most kindly supplied the needed article. *Morale*: While making use of friends to assist in carrying our apparatus, don't trust to them to see that nothing is left behind.

Bothwell Castle and its surroundings afford ample scope for much picturesque work, including, as they do, the grand old pile, groups of noble trees, and beautiful windings of the Clyde; but in consequence of the time lost in the search for sheltered nooks and corners, a comparison of notes at the end of the day showed that only thirty-nine plates had been exposed. It is, however, gratifying to state that, so far as we have learned, they have nearly all turned out well.

At five o'clock the party drove back to Hamilton, where full justice was done to a good dinner prepared by mine host of the Commercial Hotel, and, starting at 8:30, they reached Edinburgh shortly after ten o'clock, thoroughly pleased with the enjoyment of the day.

MANCHESTER PHOTOGRAPHIC SOCIETY.

THE last meeting before the vacation was held at the Memorial Hall, on Thursday evening, the 8th inst., ALFRED BROTHERS, F.R.A.S., President, in the chair.

After the routine business had been disposed of,

Mr. POLLITT read a paper on "Swing-fronts *versus* Swing-backs."

Mr. COVENTRY exhibited a swing-front made by himself to illustrate a principle suggested by Mr. Woodbury.

Mr. D. YOUNG read a short paper on "Another Improvement in Making Oxygen," and exhibited the retort in action.

Mr. NORON said that the specific gravity of oxygen plugs was greater than that of the same mixture in powder, and, bulk against bulk, yielded more gas.

Mr. W. J. CHADWICK showed his oxygen machine, improved so as to be absolutely safe, and made some gas to exhibit the action of the spring arrangement in his retort.

THE PRESIDENT exhibited an instance of a negative having been changed into a positive by the action of light before fixing; also a Daguerrotype plate iodized about twenty years since, which he accidentally found was still sensitive.

Mr. J. B. ROBINSON had sent a sample of waterproof paper suitable for the making of developing tray, also a tray of the same material which had been full of water half the day.

Mr. CHAPMAN exhibited a specimen of glass-wool, which he said was useful for filtering purposes.

Mr. COOTE showed some good examples of clouds printed on ferro-prussiate paper, which he used as a sort of index for his cloud negatives.

Mr. POLLITT exhibited some of his splendid interiors of the New Town Hall, taken on wet plates, with a swing-back camera. Some of the negatives were exposed five hours.

Mr. W. J. CHADWICK presented the Society with a pair of legs and a new box for the sciopicon, and was awarded a vote of thanks.

A similar compliment was paid to the other gentlemen who had contributed to the interest of the meeting.

PHOTOGRAPHERS' BENEVOLENT ASSOCIATION.

THE third annual meeting of the members was held at 174, Fleet Street, on Monday, May 7th, Mr. W. S. BIRD in the chair. The minutes of the previous meeting having been read and authenticated, the Secretary was called upon to read the report and statement of accounts for the past year. After a few remarks from the Chairman, the report and balance-sheet were adopted.

The meeting then proceeded to the election of officers. The following gentlemen were elected:—

Vice-presidents.—Rev. F. F. Statham, M.A., F.G.S.; J. H. Dallmeyer, Esq., F.R.A.S.

Treasurer.—H. Baden Pritchard, Esq., F.C.S.

Auditors.—G. Taylor, Esq., Mr. Sisman.

Board of Management.—W. S. Bird, Esq. (Chairman), Mr. W. M. Ashman (Deputy Chairman), Messrs. W. S. Atwood, H. J. Burton, T. Bolas, J. D. Tague, J. A. B. Hall, T. S. Hicks, E. Lavender-Rheinslander, H. J. Thorne, and S. Tyler.

The Board of Management having selected the candidates from the number of applications for the post of Secretary, each candidate was separately questioned by the Chairman and Members respecting their ability to fulfil the office if elected. Upon their retiring, the votes were unanimous for Mr. Harland to be Secretary for the year ensuing, and to be remunerated by a small salary and commission. As a further means of enhancing the funds of the Society, the Chairman advocated the employment of a paid agent to introduce the features of the Association in the provinces, as the objects of the Association were not thoroughly understood in many places. It was finally resolved that the Chairman be empowered to arrange with a competent traveller to canvass for members and donations in the provinces, and that the remuneration should be in form of commission.

Some members then advocated some alterations in the rules. Finally the following alterations were passed:—Rule 2. The word *profession* struck out and *Association* substituted, and add at the end, *to duly qualified applicants*. Rule 4. That *benefit* be inserted between *every* and *member*. That *two years* be altered to *twelve months*. Rule 5, line 5. That *twelve months* be altered to *six months*. Rule 10. The above alterations being carried, the fifth line from the bottom is superfluous, its erasure giving subscribers a preferable claim. Rule 16. That the Board of Management consist of *ten* members instead of *fifteen*.

After the usual vote of thanks to the Chairman for presiding, and to other gentlemen for their services during the past year, the meeting was adjourned.

FRENCH PHOTOGRAPHIC SOCIETY.

A MEETING of this Society was held on the 6th inst., M. PELIGOT in the chair.

THE PRESIDENT announced that he had received from H. E. the Russian Ambassador, the Minister of War, and from the Minister of Public Works, letters of thanks for the report which had been drawn up by the Society on the occasion of the last exhibition.

A letter was read from the Minister of Public Instruction enclosing authority for the payment of five hundred francs, being the prize promised for the best dry-plate process submitted. [This prize, it may be remembered, has been awarded to M. Chardon.]

THE SOCIETY requested the President to thank the Minister, and to take steps for the institution of another competition.

M. DAVANNE observed that the reason of the Government for favouring the elaboration of photographic processes was to be found in the fact that it was so useful for scientific missions.

This circumstance, the PRESIDENT said, should be borne in mind in any future competitions.

M. SAHLER forwarded a note relating to instantaneous photography.

M. DAVANNE, on behalf of the Duke of Chaulness, presented a print in colours obtained by the process of M. Cros.

M. ROBERT, the Director of Sevres Porcelain Factory, offered for the acceptance of the Society a porcelain portrait of M. Poitevin. The plate which had served as matrix was secured by the moulding and relief process indicated some years ago by M. Poitevin.

M. ANDREA called attention to a number of the PHOTOGRAPHIC NEWS containing an article by M. Peltz on the dissolution of lac in alcohol. Abstracts from other foreign journals were read by M. Andrea.

M. DAVANNE called attention to the nomination of a commission by the Minister of Public Instruction to discover how far the employment of photography in copying the various public collections depends upon that minister. M. Davanne read the report drawn up by M. Ferrier and himself, who had been nominated to award the prize for the best dry-plate process.

Afterwards the PRESIDENT handed to M. Chardon the prize which had been awarded him.

M. CHARDON thanked the Society, and gave a demonstration of his process before the members.

The proceedings then terminated.

Talk in the Studio.

ULTRA-VIOLET SPECTRA.—In a recent communication to the Belgian Academy, M. van Monckhoven describes some improvements in the photographic reproduction of ultra-violet spectra of gases. He employs two large Goussier tubes, placed parallel, and communicating together by a capillary tube at right angles to them. The spectroscopic consists of three sixty-degree prisms of Iceland spar, cut so that the bisector plane of each of their dihedral angles is parallel to the optic axis of the crystal. With such prisms the ordinary and extraordinary spectra do not encroach on one another. The axis of the capillary tube is then made to coincide exactly with that of the collimator of the spectroscopic, and the intensity of the light, which can be utilized during passage of the current from a Ruhmkorff coil, is found to be very much greater than if the tube were placed, as usual, perpendicularly to the axis of the apparatus. The author recommends using a plate of quartz in place of one of the large tubes of glass, as to prevent too great absorption of rays of high refrangibility. To give an idea of the exactness with which even the most refrangible bright lines are reproduced, M. van Monckhoven presented three plates representing the solar spectrum, the bright lines of hydrogen combined with those of aluminium (of which the electrodes were formed), and the bright lines of a solar protuberance.—*Nature*

A YORKSHIREMAN'S IDEA OF PHOTOGRAPHY.—The *Darlington Times* says:—"At the Stokesley County Court, a plaintiff who lives by retailing provisions at Lundale, near Guisborough, stated that the defendant in his case is a 'fittograffer chap.' On being questioned by the Registrar, he explained that a 'fittograffer' is 'a chap as takes shadders.' Judge Turner should publish some local jottings of his experience, which must be full of amusing incidents."

PHOTO-STEREOTYPING.—The name of photo-stereotyping is given to a new and its ingenious process of its kind just introduced. A sheet of ordinary plate-glass, larger than the picture to be reproduced, is coated, in a dark room, with a solution made by dissolving one ounce of potassium bichromate in fifteen ounces of water, warming gradually, and then adding two ounces of fine gelatine, and filtering through linen at the boiling heat. Now, a diapositive is taken from an ordinary negative, and laid with the collodion side to the gelatine face of the prepared plate, in diffused light, for ten to thirty minutes. The plate is then taken from the frame in the dark room, and washed with water for five or ten minutes till the relief is wholly developed, after which it is dried with filtered paper and coated with glycerine by means of a camel's hair pencil, and the excess of liquid is removed with filter paper. From the plate prepared according to this process a cast is made, in plaster of Paris, of the thickness or consistency of oil, and from the plaster cast thus obtained a metal one may be taken in the usual manner.—*St. Louis Practical Photographer*.

To Correspondents

FRED WARNER.—Mr. Robinson's "Pictorial Effect in Photography" is out of print. 2. Your question as to glycerine is too vague. You ask what quantity of glycerine is required to forty ounces of silver bath. As a rule no glycerine is required. It is not customary to add it to a silver bath. It has been proposed, under certain circumstances, to add a little. It has been proposed, in cases of long exposure in warm weather, when the silver solution is apt to dry upon the plate, to add a little glycerine to check such tendency to dry. The quantity in such case should be ascertained experimentally, beginning with, say, one ounce of glycerine to the forty ounces of bath, and adding more until the effect was obtained. 3. Registration will not prevent piracy; but it will, doubtless, tend to check it. Registration is a necessary preliminary to legal redress in case of infringement of copyright. We do not know of any studies of grouping you can purchase.

J. B. ROBINSON.—We are obliged for the sample of water-proof paper, which it is probable, we think, may be found very useful for many purposes in photography. Dishes, trays, baths, &c., may easily be built up with such a material, and we doubt not that various other purposes will be found as occasion arises.

CONSTANT SUBSCRIBER.—Your letter must have gone astray, as we have no queries with such a signature. Repeat your questions, and we will answer them.

DR. MANTELL.—Some samples of pyroxyline do not readily dissolve in ether alone, but dissolve at once on adding alcohol to the ether. Try adding alcohol. If the pyroxyline still remain undissolved, we fear that it is an imperfect sample, and unless it can be exchanged by the manufacturer, must be thrown away; we do not know of any method which will make it soluble. It is to be regretted that very few manufacturers of collodion care to sell pyroxyline, and hence there is no certainty of getting good samples. The best kind of pyroxyline for emulsions is that made at a high temperature with weak acids. We have always found it necessary to prepare our own pyroxyline when we required any special quality.

D. R.—The best mode of dissolving glass in spirit to make a mounting material is, first soak the glass, drain away all water, and dissolve by the aid of heat. Then add the spirit—methylated will serve—a little at a time, and keep stirring. It will, after becoming cold, require very slight warmth to redissolve it sufficiently for mounting purposes.

M. F. L.—When using very highly albumenized paper, which tends to curl very much when dry, it is best to mount the prints when slightly damp. It saves much trouble, and prevents the cracking of the albumen surface. When mounted, place the prints under pressure until they are rolled or burnished.

J. JUNK.—A single lens will answer every purpose for simple landscape work. The wide-angle landscape lens, of the maker you name, will take in quite as wide an angle as you require.

AMATEUR PORTRAITIST.—It is possible to produce portraits in the open air. Select, if possible, a place where direct sunlight is cut off by a building or wall, and, if possible, use a canopy overhead to shut off direct top-light. The skilful use of screens will effect much.

Several Correspondents in our next.

METEOROLOGICAL REPORT FOR APRIL.

BY WILLIAM HENRY WATSON, F.R.S., F.M.S.

Observations taken at Braystones, near Whitehaven,
36 feet above sea-level.

Date.	BAROMETRIC PRESSURE.			TEMPERATURE (IN THE SHADE).			REMARKS.
	Morning.	Noon.	Night.	Morning.	Noon.	Night.	
1	30.81	29.84	29.80	44°	45°	43°	Fair, but cloudy
2	29.70	29.62	29.47	43°	46°	46°	Drizzling rain a.m. and p.m.
3	29.32	29.14	28.49	43°	47°	47°	Rain all day. Very windy at night
4	28.90	28.30	28.77	46°	55°	44°	Rain from noon. Heavy dark clouds
5	28.97	28.99	29.16	40°	52°	45°	Fair during the day. Thunder, with showers, at night.
6	29.22	29.27	29.30	49°	50°	40°	Fair, generally clear
7	29.38	29.39	29.40	60°	51°	45°	Shower in the afternoon
8	29.44	29.45	29.45	63°	54°	48°	Fair, clear, and sunny
9	29.41	29.42	29.40	60°	55°	47°	A little rain a.m. and p.m.
10	29.39	29.37	29.41	48°	56°	50°	Fair, clear, and sunny
11	29.55	29.58	29.76	44°	45°	40°	Fair and sunny
12	29.86	29.85	29.80	40°	48°	40°	Fair and clear
13	29.77	29.78	29.80	45°	45°	45°	A little rain a.m. and p.m.
14	29.95	29.96	29.99	47°	50°	47°	Rain a.m. and p.m. Wind at night
15	29.78	29.68	29.58	46°	56°	47°	A little rain a.m. and p.m. Very strong wind all day
16	29.47	29.48	29.60	48°	48°	—	Fair. Very strong wind. Gloomy
17	29.65	29.70	29.70	50°	43°	39°	Fair. Windy. Gloomy
18	29.68	29.67	29.79	53°	42°	40°	Fair, generally sunny
19	29.78	29.83	29.80	54°	43°	40°	Fair, generally gloomy
20	29.99	29.96	29.90	41°	49°	47°	Fair, but gloomy
21	29.70	29.61	29.50	45°	48°	48°	Rain a.m. and p.m.
22	29.15	29.40	29.34	—	49°	46°	Heavy rain at night
23	29.34	29.41	29.40	47°	51°	50°	A little rain p.m.
24	29.48	29.72	29.60	40°	57°	45°	Fair. Windy at night. Gloomy.
25	29.71	29.76	29.83	50°	58°	41°	Fair and sunny
26	29.82	29.83	29.84	40°	—	42°	Fair, generally gloomy
27	29.80	29.79	29.72	41°	53°	42°	Fair and sunny
28	29.76	29.76	29.74	44°	47°	43°	Fair, generally sunny
29	29.70	29.74	29.89	44°	44°	43°	Fair, but gloomy
30	29.01	29.04	29.16	43°	41°	39°	Fair, but gloomy

Summary.				Mornings. Noons. Nights.		
Highest temperature observed	53°	58°	48°
Lowest ditto	29°	41°	38°
Mean ditto	43.5°	50.3°	43.7°
Mean of all observations	46° 6'		

NOTES.—By referring to the above it will be seen that the temperature during the month of April this year has been considerably below the average. Although early in the year, the weather was very mild, yet as the spring advanced it has become more severe. The trees are ready to burst at once into foliage, but are being checked by the cold mornings and nights, and east winds, which even now prevail.

The Photographic News, May 25, 1877.

PHOTOGRAPHY IN AND OUT OF THE STUDIO. MANUFACTURE OF CELLULOSE—PHOTOGRAPHERS' BENEVOLENT ASSOCIATION—OUR ILLUSTRATED NEWSPAPERS.

Manufacture of Cellulose.—It is generally supposed that the photographer, the surgeon, and the soldier are the chief consumers of all the guncotton that is manufactured nowadays. The vast quantities of collodion that are every day required to keep the photographer going in his work must alone necessitate the preparation of a good deal of pyroxyline, and, of late, the demands on the material for military purposes has largely increased the scale of its manufacture. But there is another channel yet for the consumption of guncotton, namely, in the production of a material termed xylonite, or, as a modification, is called celluloid. It is now some years since guncotton was first used in this manner, a sort of imitation ivory being prepared by its means, which is largely employed as a substitute for the veritable tuak. It is only recently, however, that any great energy seems to have been exerted in the matter, and while the factory originally established in this country is more busy than ever in the manufacture of guncotton articles, in America there are several such establishments in existence, one notably at Newark, in the United States, which is about to start a branch factory in Paris. As we have said, the material is now known generally as celluloid, and it is under this name that its manufacture is being vigorously prosecuted. It is moist guncotton, mixed with camphor, and probably certain white pigments to give it an ivory look, the product, when in the shape of brush handles, pianoforte keys, billiard balls, and the like, being hardly distinguishable from ivory, except in respect to its odour, which is of an aromatic nature. Instead of taking cotton wool or yarn for the preparation of the material, as is usually done in the manufacture of pyroxyline, it is pulp, or rather paper, that is acted upon by the acids in the production of celluloid. A roll of endless paper is made to unroll, and as it does so there falls upon it a liquid stream composed of five parts of sulphuric acid and two parts nitric acid. This mixture transforms the paper, or cellulose, into a sort of pyroxyline. The paper is then pressed to remove the excess of acid, and then washed to further remove all traces thereof. After drying, this endless sheet of guncotton is broken up in a mortar, mixed with camphor, put under high pressure, and dried in a hydraulic press between sheets of blotting-paper. After more grinding and pressing, it is obtained in beautiful transparent plates of a very elastic nature, in which condition it is ready to be applied to the many and varied uses to which it is put.

Photographers' Benevolent Association.—The Photographers' Benevolent Association has just issued its report for the past year, and we regret to see that the institution is not receiving the support from photographers in anything like the degree it deserves. We note that during the year seven cases of distress were relieved to the extent of £16 6s., while the subscriptions from ordinary members amounted only to £14 19s. 6d. There is still a balance in hand, we see, of £50, but this money is due to subscriptions from honorary members and other sources. The ordinary expenditure of the Association is heavy in comparison with the receipts, but it no doubt represents the minimum at which such an affair can be kept going, and we presume that if the number of members were increased tenfold, there would be no need for any augmentation in the expenditure. It is, however, for photographers to say whether the Association shall be a prosperous one or no, and certainly the number of ordinary members must be greatly increased before the body can exercise any great degree of usefulness. The benefits which the Association desires to secure to its members are, according to

the report, substantial relief when a member needs it; railway fares, to enable a member to reach a situation at a distance; and engagements for assistants out of work.

Our Illustrated Newspapers.—Painters and draughtsmen are so hard upon photographers at times that it is well occasionally to point out that the works of the former are not altogether immaculate. Sketches in our leading illustrated journals are contributed by men of some standing in their profession, and for this reason the pictures are usually regarded by the general public as just representations of the scenes they are intended to depict. But that this is not always the case is evident from two large pictures that have recently appeared. One of these represents the coal mine in the Rhondda Valley which was flooded some weeks ago, and the other showed the monster 80-ton gun immediately after firing. Everybody who read the exciting story of the release of the colliery from their entombment is aware that the tunnel which was cut so rapidly for their relief measured no more than two feet six inches, or three feet, in height, and that the men who cut the coal had to lie or crouch down while at their work. And yet we are shown, in the representation of the affair given us in the illustrated papers, a passage in which the men at work cutting the coal can not only stand upright, but have many feet above their heads to spare. The picture of the firing of the 80-ton gun at Shoburness is just as absurd. The gun recoils something like forty feet when fired, and jerks back at the moment of discharge with terrible energy, as may well be supposed when we remember that the amount of powder burnt at a time is upward of 300lb.; and yet we are treated to the picture of a man standing up behind the gun in the most unconcerned manner, while at the same time smoke is issuing from the muzzle of the weapon. We say nothing of the crowd of spectators standing around within a foot or two of the cannon, although at the time the picture was put before the eyes of the public it was known that a flaw or crack existed inside the gun, and under these circumstances no one would certainly be permitted to view it at close quarters at the time of its discharge. Indeed, to judge from the accounts in the public press, both artillerymen and visitors have been exceedingly shy of the weapon since its weakness was discovered, and have all gone under cover of late when the signal to fire was given. One of these days, perhaps, we may have an illustrated paper made up of pure photographs only, a publication which, if not, perhaps, quite so interesting as our present journals, will, at any rate, have one element in its favour, that of truth. How much more vivid than all descriptions, or pencil sketches, for instance, would have been a photograph taken by magnesium or electric light of the cavern in which the Rhondda colliers were imprisoned, and of the tunnel cut for their relief, together with pictures of the pitmen in their work-a-day attire! The oft-repeated question, "Is it true?" would never then be asked, for the pictures before our eyes would carry conviction with them. Already, however, photography has done much to keep the artist in the right path, and to prevent him from using his pencil too lavishly, and drawing upon his imagination. We have for some time past ceased to have books of travel published with wonderful illustrations, for, thanks to the travelling photographer, we have become acquainted with a good many natural wonders. The highest waterfall in Europe, that of Gavarni, in the Pyrenees, which used to be drawn as a veritable cataract dashing down from the clouds, and making a clear leap over the rocks of 1,200 feet, becomes another matter altogether when we see a photograph of it. The precipitous wall of rock over which it tumbles may be the height mentioned, but then the water does not fall (or has not fallen since the days of photography) clear of the background, but is broken in more than one place, while the stream is so small that, under ordinary circumstances, it is hardly observable at a distance. These were

facts which the traveller no doubt forgot to tell the artist when the latter drew the picture, and hence the misrepresentation finding its way into print.

THE SWING FRONT VERSUS THE SWING BACK.

BY J. POLLITT.*

THE recent appearance in the columns of the *British Journal* of two or three letters following an editorial article some weeks previously, on the subject of swing fronts and swing backs, seems to favour the supposition that the use of such appendages is, in certain quarters, somewhat imperfectly understood.

When Mr. M. Noton brought his ball-and-socket arrangement before a meeting of the Manchester Photographic Society two or three months ago I ventured to remark that, although the same ends could be equally attained by either swing back or front, or ball-and-socket lens tube, still I had found in practice that the swing back was a much more convenient arrangement, because, for reason No. 1, the axis of the lens thereby always preserves its parallelism with the base line of the camera; and, for reason No. 2, that a much greater latitude is necessary in the sliding up and down of the panel carrying the lens in the case of a swing front than is required when the swing is attached to the back. This is a sufficiently fatal objection when a Kinnear camera is used, because it will be found that the folds of the conical bellows-body will cut off a good deal of the margin of the picture when the lens is raised considerably over the centre.

The dispute about the looking-glass principle is simply a storm in a tea-pot; for it makes not one iota of difference whether the swing be constructed on the looking-glass principle, or whether it be hinged at the bottom in the form of an inverted easel, and in accordance with a very neat arrangement adapted by Mr. J. Rogerson to the cameras made by him many years ago. The right inclination of the plate can be obtained just as easily in one case as the other, and it is simply a question of economy in bulk or convenience in construction as to which of the two methods is chosen. In either case the focussing must be finally and carefully done after the swing is adjusted to the proper angle.

The real use of the swing is, however, a subject of much greater importance than the question of mechanical construction; and, as I consider too little has been said about the former and too much about the latter, I hope it will not be considered gratuitous on my part if I presume to give a short lesson on the subject deduced from my own experience, leaving those interested to use their own discretion as to form and arrangement of apparatus.

Let it be supposed that the subject to be photographed is the front elevation of a tall, narrow building, say ninety feet high, and that the exigencies of the case require the camera stand to be placed on the ground floor at a distance from the object only of eighty or one hundred feet. Supposing the lens to be about three feet three inches from the ground, it is evident that an imaginary line drawn from the centre of the lens to the summit of the building will be considerably longer than another imaginary line from the centre of the lens to the base of the building; and, therefore, by reason of the focus of the lens being regulated inversely by the distance of the object from the lens, it will be found that the lower part of the focussing screen, on which is depicted the upper portion of the picture, will be required to be brought nearer to the lens than the upper part of the screen on which is depicted the base and foreground. The simplest way of meeting the difficulty is unquestionably by a swing-back arrangement to adjust the screen, so that all parts of the subject are brought into the best focus at one and at the same time. This being done, and the camera absolutely levelled, it

will still be found that the parallelism of the perpendicular lines on the ground glass will not stand the test of a carefully-applied measuring rule. The reason is obvious. By means of the swing we have shortened the focus for the upper part of the object, and, in consequence, reduced the scale of the picture, and the distance between perpendicular lines as compared with the lower portion so much nearer to the lens; so that, after all possible care with spirit level and swing, it will be seen that there is still a falling inward of perpendicular lines approaching the summit of the building, which, however, can be counteracted by a slightly downward tilt of the camera bodily. This slight movement should be sufficient to cause the upper lines to diverge to just the extent only to which their greater distance from the lens would make them converge, supposing the camera to be perfectly level.

To the photographer who is thoroughly initiated in all the difficulties of architectural work much that I have said will doubtless seem commonplace and self-evident enough; but I was somewhat surprised that one of the writers above referred to should recommend, as a means of preventing distortion in architectural views, "that the camera must first of all be placed perfectly level, the greatest care being taken that it be not tilted. Next, the lens must be turned or tilted upwards, in the case of a swing front, in the direction of the upper part of the building, assuming it to be a lofty one," &c.

Now these instructions are so at variance with what the case demands, that I am inclined to think the writer in question has either penned them in a moment of forgetfulness, or otherwise has not weighed the subject well over in his mind beforehand; for it is evident that in the turning of the lens upwards, by either a swing front or ball-and-socket lens tube, the result will be exactly tantamount to swinging the back forward—that is to say, it will bring that part of the focussing screen on which the longer pencils of the basement and foreground fall nearer to the lens, and that part of the screen receiving the shorter pencils of the upper portion will be thrown farther off, so that by this method it will be impossible to get either freedom from distortion or universal sharpness over the field of view.

Camera Body.

A Lens turned upwards. B Basement and foreground. C Summit of building.

The accompanying sketch will show that, by turning up the lens, the image—say, of the finial of a tall spire—will be formed considerably short of the focussing screen at the lower part, and the image of the foreground will only be sharply defined at a distance outside the screen on the upper portion.

ANOTHER IMPROVEMENT IN MAKING OXYGEN.

BY DAVID YOUNG.*

AT our last meeting Mr. M. Noton gave us to understand that chlorate of potash and black oxide of manganese could not be used conveniently with the portable apparatus until it had passed through the process of being kneaded into cakes or plugs, and then baked. This, I believe, is quite true of every portable oxygen generator with the exception of the one before you; and, as I was the first to show that only one generator was required to be used with the portable oxygen apparatus if it was of the proper construction, I think I am also the first to point out that the oxygen mixture can be used with the portable apparatus without its having to pass through the kneading process.

I will now show you my method of making oxygen

* Read before the Manchester Photographic Society.

without having to pass through that dirtiest of dirty jobs, making the oxygen mixture into cakes or plugs; and I would take this opportunity to direct your attention to the very great simplicity of the whole. You may keep the oxygen mixture in a bottle or any thing you wish, and you have simply to pour some into the case, and put the case into the generator. When it is exhausted, you will see how easy it is to withdraw, or perhaps make it withdraw itself.

A few of the advantages I claim for my patent apparatus are follow:—First, the great simplicity and portability of the apparatus. The one before you will generate eight of ten cubic feet of oxygen per hour, and can be carried in the pocket. This, I think you will admit, is a great improvement. Second, greater safety, as the oxygen mixture is placed in an inner case, and, therefore, cannot fly off in pieces, and stop the outlet. Third, the inside of this generator is kept cleaner than any other, because the oxygen mixture is not in contact with it. Fourth, you may avoid the mess of making the oxygen mixture into cakes or plugs, and having to bake them, and afterwards carry them as carefully as if they were eggs, for fear of breaking them. Fifth, you have the exhausted charges in a cleaner and more compact form than by any other plan.

The generator, by altering the shape of the cap, can be used vertically like the old-fashioned retort, in which case to get it to decompose an equal amount of oxygen mixture it would require to be made shorter and larger in diameter. This, of course, increases the circumference of the joint, which is a serious objection; or it may be used diagonally or horizontally, as you see it. Both these positions, I think, were first introduced by Mr. Noton, and either is better than the vertical position for other reasons

besides the one stated. For the benefit of the members not present I have made a sketch of the generator in the horizontal as well as the vertical position, which will, I think, enable them to understand the whole.

CAN PHOTOGRAPHY MAKE PICTURES?

BY PROFESSOR GREENE.*

CAN artistic photography, or, in other words, photography, be classed among the fine arts?

I am well aware that many artists, as well as some photographers, claim that it is not and cannot be so classed. I for one do not belong to that number, though I do not wish to be understood to say that every photographer is an artist, for many of them are nothing more than mechanics, and some of them very poor ones at that. But, you will say, fine art is produced only by the hand of man, and not by a machine. I will agree with you there, if you will only add the head and heart. It requires mind and soul to create fine art; if it did not, every one would or could be an artist, for there is no one so dull but he could

daub paint upon a canvas, and, I think, much easier than make a photograph. The photographer uses the camera, a machine, to make his picture; so does the painter a brush—perhaps a more simple machine. You will say the brush is guided by the hand; so also is the camera.

The camera never tells a lie: the brush frequently does. If the operator is an artist, he will give the subject an easy, natural pose, the draperies will be nicely arranged, and accessories added as required; the light will be so adjusted as to give the exact distribution of illumination and shadow, and the camera will do the rest. With him the result is as certain as with the painter; there is no chance work about it. How is it with the machine photographer? It is all chance; he is continually groping in the dark; he never knows whether his picture will be good or not until it comes out of the camera; and then he is not sure, for he is not a judge of a work of art when he sees it. He may occasionally make a good picture, but he cannot tell you how he did it; with him it is all guess work. On the contrary, the artist sees his picture before exposing the plate in the camera; he is as certain of the result before the plate is developed as afterwards. You say the photographer is only a copyist; he can only make that which is before him, or, in other words, he only copies nature, and that, you say, is not fine art. Let us read a little from Ruskin's choice selections, pages 195 to 198.

“Historical Painting.”—What do you at present mean by historical painting? Now-a-days it means the endeavouring, by the power of imagination, to portray some historical event of past days; but in the middle ages it meant representing the acts of their own days, and that is the only historical painting worth a straw. Of all the waste of time and sense which modernism has invented—and they are many—none are so ridiculous as this endeavour to represent past history. What do you suppose our descendants will care for our imaginings of the events of former days? Suppose the Greeks, instead of representing their own warriors as they fought at Marathon, had left us nothing but their imaginings of Egyptian battles; and suppose the Italians, in like manner, instead of portraits of Can Grande and Dante, or of Leo the Tenth and Raphael, had left us nothing but imaginary portraits of Pericles and Miltiades? What fools we should have thought them! How bitterly we should have been provoked with their folly! And that is precisely what our descendants will feel toward us, so far as our grand historical and classical schools are concerned. What do we care, they will say, what those nineteenth century people fancied about Greek and Roman history? If they had left us a few plain and rational sculptures and pictures of their own battles and their own men in their everyday dress, we should have thanked them. Well, but you will say, we have left them portraits of our great men, and paintings of our great battles. Yes, you have indeed, and that is the only historical painting that you either have or can have. But you don't call that historical painting. You don't thank the men who do it; you look down upon them, and dissuade them from it, and tell them they don't belong to the grand schools. And yet they are the only truly historical painters, and the only men who will produce any effect on their own generation or on any other. And the wonderful thing is, that of all these men whom you now have come to call the great masters, there was not one who confessedly did not paint his own present world, plainly and truly. Homer sang of what he saw; Phidias carved what he saw; Raphael painted the men of his own time in their own caps and mantles; and every man who has arisen to eminence in modern times has done so altogether by his working in their way, and doing the things he saw. How did Reynolds rise? Not by painting Greek women, but by painting the glorious little living Lady Thia, and Lady Thia, of his own time.

“Pre-Raphaelitism.”—Pre-Raphaelitism has but one principle, that of absolute, uncompromising truth in all

* Read before the Chicago Photographic Association.

that it does, obtained by working everything, down to the most minute detail, from nature and from nature only. Every pre-Raphaelite landscape background is painted, to the last touch, in the open air from the thing itself. Every pre-Raphaelite figure, however studied in expression, is a true portrait of some living person. Every minute accessory is painted in the same manner."

It is not my intention to discuss at very great length the subject whether photography is a fine art or not. However, I think we are entitled to the credit of being historical artists, as we furnish and will hand down to posterity more portraits of men and women "in their every day dress" than all other artists put together. But what I wish to call your attention to is some of the errors in the practice of photography, and what I consider our stumbling-block. One of them is the number of accessories that are put in to fill up the picture. They remind one of a second-hand store or a pawnbroker's shop; and the worst of it is that the authors of some of these photographs claim to be A No. 1, and the leading photographers in this country. Had they been educated in art, they would never have committed such errors. Another, which is more fatal to our claim as artists, is the attempt to make a combination picture by printing ~~from different negatives, figures, &c., on one sheet of paper to form one picture, by the aid of an artist working in the foreground, background, &c.~~ To illustrate this error I will refer to one or two pictures that have been made in this city lately. The first one alluded to is supposed to be a regiment of soldiers, not on drill, or in the fierce struggle of battle, but at rest. To me, however, it is not at rest; for I think it almost impossible to photograph a young volunteer at rest; he will be stiff and awkward, do what you will with him. This is enough to destroy all the art or interest in the picture; but we might excuse this fault if there were not others so gross as to defy all the rules of art, and to utterly destroy all the value there is in the picture as a work of art. Each figure in it—say five hundred, more or less, as may be—has a point of sight of its own. Who ever heard of an artist painting a picture with five hundred distinct points of sight? Every one knows, who knows anything of art, that there is not and should not be but one point of sight in a picture. The lighting of the figures, also, is as bad as the posing and drawing, striking some from one and others from an opposite direction; in fact, there are all kinds of cross lights, hardly any two of them agreeing. There are other errors equally as bad; but it is useless to criticise such pictures, for every one can see at a glance that it is impossible to make them in this way and conform to the rules of art. It makes no difference how well the artist has drawn in his portion of the work, the camera has placed a point of sight back of each figure, that he cannot work out.

I do not wonder at an unwillingness to admit us to the position of artists so long as we manufacture such pictures and claim them to be artistic. What photographers ought to do is to classify their work, and have a certain standard by which to admit it as artistic, the same as with the painters; then we might have some claim to the name of artists.

The other picture I will refer to is our Fire Department at work. It has the same faults, so far as art is concerned, as the other, which makes it unnecessary to say anything about it in this respect. As a piece of merchandise it has two features to recommend it which the other did not have: first, it shows action, while the other does not; but the most valuable feature to any one whose portrait is not included in the picture is the artist's work, which renders it a memorial picture of the great fire of October 8th and 9th, 1871.

Pictures of this class would be all right if placed where they belong, as articles of merchandise, but not as works of art.

PHOTOGRAPHIC FASHIONS IN NEW YORK.

MR. FRITZGIBBON, in the *Practical Photographer*, gives, as he promised, some hints as to the fashions prevailing in the best photographic establishments. Here are hints from New York:—

"Of so great importance have become the backgrounds used in photographic portraiture, that we have selected them as the subject for this month's consideration.

"Winter, 'lingering in the lap of May,' is illustrated at Sarony's, where a dreary waste of snow, covering hill, dale, and river, is depicted on one of the backgrounds, still to be seen under his easterly skylight. This has done good service during the closing winter months. With it, children sliding down a hill, young gentlemen skating, and many other scenes incident to wintry weather, have been successfully represented. At this gallery of art, interior backgrounds for full length figures are mostly of the renaissance school, executed with great dash and vigour. There is, however, an indication that the Eastlake or modern Gothic will be used to some considerable extent after May 1st, at the new gallery on Union Square. A handsome conservatory is frequently used for daintily dressed young ladies. The head and bust backgrounds are a very light one, with shadings similar to the standard Rembrandt, and rich shaped woollen one for three-quarter length and standing figures. For children, under the special quick skylight, is used an interior with a plain wall, an open door on the left, and a cabinet of bric-a-brac on the right, all somewhat in miniature. The highest form of theatrical portraiture still forms a part of the business of this gallery. Backgrounds are painted for this branch from sketches which have been made in the theatre during the progress of the play, set pieces, arranged as on the stage, being frequently used.

"Rockwood uses a tapestry interior, in conjunction with an antique cabinet, for imperials; and for groups, a background representing a room with massive marble columns. The centre of this ground, being quite plain, is used for three-quarter lengths, sitting and standing.

"At the new gallery of Fredericks and O'Neil, Broadway, corner of Ninth Street, a seashore, in connection with artificial rocks, is used almost exclusively for children, many beautiful results attesting their value. A garden, with dense foliage, is used for adult standing figures.

"Pearsall (Frank E.), of Brooklyn, has hit upon an entirely new idea. For three-quarter length standing figures he uses a background about five feet in width by seven in height, arranged to slide up and down in a frame, the centre of which is a charming bit of sky, sea and shore, painted within a space of from three to four feet in diameter, the edges being lost or vignetted into the rather light neutral tint covering the balance of the canvas. This background is used principally in his non-distorted prints, also an invention of his, and, we understand, protected by letters patent. His pictures are pearly, have an air of elegance, and are strong and rich when the subject has worn dark drapery.

"At 707 Broadway (Mora's) we find an unusual number of backgrounds in use, the custom being to introduce from one to two or more new ones monthly. They are stretched on frames, one on each side. These frames have no permanent feet, and are hung, when not in use, side by side to hooks in the ceiling near the south wall of the operating room. About twenty backgrounds are thus arranged, and a moment or two suffices to take one down, attach portable feet, and place in position. A great variety of exterior and interior scenes affords an opportunity for the artist to select a background in accordance with the style of dress and social standing of the subject. A new feature at this establishment is a series of eight backgrounds, each five feet by six feet, for the various positions of light and shade desirable in head and bust pictures. Out-door and in-door accessories, real and imitation, are highly esteemed by the proprietor.

"At the Kurtz gallery, for head and bust pictures, the concave papier mache background (the well known invention of Mr. Kurtz), painted a canary yellow, is used. An elaborate interior exhibited at the Centennial by Seavey is one of the latest acquisitions. From twelve to fifteen backgrounds, each designed for a special use and place, are in daily use, rustic accessories and fine cabinet furniture playing important parts. So far as we can learn, the painted backgrounds in use in the above galleries are from the studio of Mr. L. W. Seavey."

HUSNIK'S IMPROVED LICHTDRUCK.*

Thick patent plate glass must be employed, or thinner glass netting on a thick plate. These must be very carefully ground with emery, the grain left upon the glass having some effect upon the print. After being perfectly ground, it is well to treat the plates with an ammonia or alkaline solution.

The first preparation applied to the plate consists of:—

Fresh white of egg	7 parts
Silicate of soda or potash solution	...	3	"
Distilled water	8 to 10 "

The silicate solution is of the consistence of oil as it is to be met with in commerce. In hot weather more distilled water is required than in the winter months; the white of egg must be free from yolk.

After standing four to six hours, the clear part is poured off and carefully filtered twice.

The plate in a dry condition is freed from dust with a brush, and placed in a horizontal position. Some of the above mixture is applied to the margin farthest from the operator, and then spread over the surface by gradually tilting the plate and employing a strip of paper, taking care that the liquid does not run too fast. By liberally breathing upon the glass the operation is greatly facilitated. A rapid pouring off of the liquid at one of the corners prevents the formation of air-bubbles, which may also be overcome by a second rapid application of the mixture. The plate is ready next day, when it is dry, or may be preserved some time.

Before the gelatine solution is applied, the plate is washed under a stream of water, and finally rinsed with pure water, which removes most of the albumen and alkali; unless this is done the plate will have no stability. Six parts of fine gelatine are put into four parts of water, and the vessel containing it put upon a water-bath and finally brought to boil. Then one part of bichromate of ammonia is added, and the liquid brought up to its original volume by the addition of spirits of wine. Bubbles which are formed on the addition of the spirit disappear when the liquid is stirred, and the latter should further be filtered. It is kept in a warm condition for application to the glass plates. The latter are dried in a drying cupboard, dusted with a brush, and are then coated with the gelatine solution as if it were collodion. The gelatine runs smoothly over the plate, without the formation of bubbles, and is poured off at one corner without difficulty. The plate is then put into the drying cupboard, standing at an angle of 10°, and when dry a second coating is applied. In returning to the drying cupboard the plate should be reversed, and what was top in the first instance should be bottom in the second. The gelatine solution, by reason of the spirit it contains, dries very rapidly. Afterwards the plate is put by in a dark place; it may be printed at once, or will keep in good condition for a week in summer and longer still in winter. The drying cupboard should be maintained at about 45° Reaumur.

The dry plate is exposed under a negative for a quarter of an hour in the sun, or an hour to diffused daylight. If microscopic sharpness is desired, diffused daylight is preferable, and gives deeper shadows and better half tones. If a proper Lichtdruck printing frame is not at hand, an ordinary frame may be employed, the plate being covered

with a black cloth to prevent any reflection of the rays through the glass. The exposure is regulated by means of a photometer, unless the printer has experience in the matter. If the impression is to be printed with a margin, a mask of proper size is put over the frame during the operation of printing.

The plate is now put into water to soak, so that the unchanged bichromate may be removed; it is permitted to remain immersed for some time, the water being frequently replaced. A remarkable change now comes over the surface of the plate, for there appears a very fine grain, which is sometimes imperceptible, except with the aid of a magnifier. The grain extends over the whole surface of the plate, but it is more frequent and vigorous in the shadows, and lighter and less frequent in the high lights. An examination of the high lights will show whether the bichromate salt has all been washed out, and when this is the case the plate is allowed to dry. Afterwards it is put into water again for three or four minutes, and then placed upon an even lithographic stone, or, better still, upon a well-ground glass plate, resting upon an even basis. The wet plate attaches itself firmly to its bed, and may forthwith be printed from. If preferred, it may be put into an ordinary plaster of Paris bed, like a lithographic stone.

If the plate has been dried too slowly (the cupboard not being warm enough, or without being placed in a cupboard at all) the surface will possess little grain, or even none at all. Plates of this description are very troublesome to print, and soon give flat monotonous pictures. Grain is absolutely necessary, and a good plate, when the roller is passed over it, will emit a peculiar sound due to the roller tearing away from an infinite number of little points. When no grain is present, the roller passes over the surface without any noise.

A good plate is, therefore, to be recognized on inking, and takes the ink rapidly and well. Too coarse a grain is, however, to be avoided, and only arises when the gelatine film is too thick; impressions taken from such a surface do not appear so perfect as in the case of a fine grain. The print should appear very similar to a silver photograph in respect to fineness and delicacy, and the grain should be apparent with a magnifier.

Plates with coarse grain are sometimes desirable, as impressions from them can be transferred to zinc or stone, and etched upon these materials. After the plate has been inked, it is rubbed no more with a wet rag, but another roller is employed, or felt, or filter paper, to apply a mixture of water or glycerine. This mixture keeps the plate moist for a longer time, especially in summer, and renders it at the same time more elastic and durable. If the plate is very wet a second and drier roller may be applied. An under-exposed plate yields light prints, while, on the other hand, an over-exposed plate produces them too dark, and with no pure lights. These defects may be remedied to a certain extent; in the former case a softer ink should be employed, and the operation of inking up conducted very slowly. In the other case a firmer ink is used, and the operation gone through very rapidly. By using two inks, one after another, the first thick and the second thin, vigorous prints with delicate gradations are to be secured. The thick ink, when applied, attaches itself thoroughly to the shadows, while scarcely adhering at all to the lights, and a second roller applied with thinner ink develops the half-tones and detail in the high lights. In this case no time should be lost in inking, but the rollers must be applied one after another as soon as the plate has been moistened. A rapid inking gives much purer whites and better half tones; on the other hand, if the operator is slow, the water partially evaporates or is taken up by the rollers, and the result is a flat and dirty impression. As a matter of course the printer should be a skilful man, so as to be capable of employing one expedient or another in manipulation to improve his prints.

(To be continued.)

ON THE FACT IN PORTRAITURE FROM UNEQUAL EXPANSION OF PAPER.

Distortion in photographic images from the use of defective lenses, or the misuse of good lenses, is a defect with which most photographers are familiar; imperfect use of lenses of short focus being one of the most common forms of the latter fault. There is, however, another source of inaccuracy, but little noticed or recognized, which is probably by far the most frequent in occurrence: we refer to the inaccuracy in proportions of the image arising from the unequal expansion and contraction of some samples of paper, arising from the ordinary and necessary operations of wetting and drying. All samples of paper, as is well known, expand when wet, and contract when dry; and if the shrinkage on drying were precisely in the same ratio as the stretching when wet, all would be well. But, unfortunately, this is not so. The contraction on drying is probably much the same in amount as the expansion on wetting the sheet; but it is not necessarily in the same direction. Released from a certain tension to which it was subject in the original manufacture, the paper frequently shrinks more in one direction than another, and hence a portrait subject to these conditions may be thinner or stouter in the print than in the negative.

We have before called attention to this fact, and entered in detail into the character of the defective results arising from it; but the subject is still, we fear, not sufficiently well understood, or sufficiently carefully considered, by photographers. We have recently received, from an experienced portraitist, four prints—two pairs—asking us to examine and note the difference in prints from the same two negatives, and printed on paper from the same batch, which, nevertheless, are very appreciably different in the proportions of each face, one of each pair being about the sixteenth of an inch longer than the other. The cause is very apparent. It is clearly due to the unequal shrinkage of the paper to which we have just referred. If each print had been printed on a piece of paper cut from the sheets in precisely the same direction as the other, each might have presented inaccuracy of proportions in relation to the negative; but the defect in each, being similar, would not have excited attention—the obvious variation in the prints being the point which strikes the observer. This is a defect which is, we fear, beyond remedy, except so far as it may be possible and desirable to examine samples of paper at the outset, and reject those in which the defect is most strongly marked. It may, in some cases, however, be made useful, where a little flattery is desirable, in giving delicacy to a broad face, or *vice versa*. Some observations on the subject by an intelligent American photographer, Mr. Carl Myer, appeared sometime

ago in our Philadelphia contemporary, which it may be interesting to reproduce here. Mr. Myer says:—

"If the printer will take a slip of sensitized paper cut from the long way of the sheet, and another cut from the short way or at right angles to the first, and print from each, using the same negatives and an oval mask, then tone, fix, mount, and finish, he will be in a position to fully comprehend the really dangerous possibility of this source of distortion. The negatives will not agree with either of the prints, while they will not agree with each other. One oval will perhaps be of the same height as the mask which formed it, but from $\frac{1}{32}$ nd to $\frac{1}{16}$ th of an inch wider. The other print will perhaps be of the right width, but considerably longer or higher. The first print will exhibit a round, fat face, while the other will be longer or more 'peaked,' neither agreeing with the just proportions of the negative. In the enclosed samples, 'Latitude' and 'Longitude,' the distortion is apparently increased by printing the broader portrait through a square or arch-top mask, while the other is printed oval; but the dividers, or measuring tools used to compare them, will detect decided distortion. In the long picture the eyes appear 'rounder,' the nose longer, and the mouth narrower, and fuller tipped. The broad picture is positively pugnacious, the phrenological organ of combativeness being apparently well developed, the nose being 'puggy,' and the mouth wide. In a profile portrait this distortion is somewhat less perceptible; still the addition of (say) the hundredth part of an inch to a man's nose is not to be sneered at.

"If an exact square is cut from a sheet of paper whose sides are diagonal to those of the square, this bit of paper will be found diamond-shaped when finished, and a print on it will be diagonally distorted.

"While we contented ourselves with the carte-de-visite, or the small head vignette, these distortions were not conspicuous; but in these later days of 'swellheads' it is so evident that I have yet to see the batch of prints made on paper more or less 'cross-grained' among which I cannot detect this difference as rapidly as I can count the finished prints.

"It is evident that the different prints cannot all be correct, while comparison with the negative by measuring tools will prove that none are correct, and this source of error having been admitted as more or less constant, it remains to be decided what shall be done with it. I have made considerable use of it in making fleshy people look thinner, and *vice versa*; and I am particular to print my pictures from certain negatives all the same way of the paper, so that the subject will have no means of comparison.

"My experiments teach me that this distortion exists in greater degree among the later brands and the so-called double albumen papers, while among both these and the thinner papers I find various degrees of difference. The distortion is also much more apparent in prints that are trimmed before printing, and mounted soon after washing or before shrinking by drying thoroughly. It is also more apparent in front views of the face. Long silvering is also an exaggerating cause, for the then very wet paper shrinks considerably in drying and before printing, and expands in washing. I recommend this matter to the consideration of photographers as a more fruitful field for possible distortion than any other ever opened to the fraternity, and as possessing some compensating advantages if judiciously handled."

THE IDENTIFICATION OF WAR CORRESPONDENTS.

It is nothing new to employ the photographic portrait as a means of identification. It was so used, it may be remembered, at the Paris Exhibition of 1867, when every season ticket holder was required to paste upon the back of his admission card a picture of himself, together with his signature underneath. In this way the check-taker at the doors had some evidence that the ticket was in the posses-

sion of its rightful owner when presented as a passport for admission. Since then the same means of permitting identification has been used; but after all it is a plan that has been rarely resorted to, notwithstanding the advantages which the method certainly possesses.

Recently, however, the method has again been resorted to, and in a more important connection than hitherto. The Russian Government had set its face against permitting war correspondents to join their army; but now, it appears, owing to the strong representations made by General Ignatieff, the War Minister has at last consented to the presence of journalists in the Muscovite camps. That the permission shall not be abused, and that only recognised correspondents shall enjoy the privilege, the Russian Government has ordered that every journalist with the armies shall wear a numbered medal, which will be delivered to him, together with an inscription showing his name, function, &c. This medal will serve him as a passport everywhere, and "it carries on its reverse a photograph of the wearer, in order to put the question of identity beyond dispute."

This regulation is, undoubtedly, a very wise one, for a photograph will do more to identify a man than all the descriptions that could be written. Moreover, a photograph is a thing easily referred to, and those whose duty it is to examine suspicious strangers, and to discover whether they are friends or foes, will be able to arrive at a conclusion more quickly. Again, the photograph has much to recommend it, from the circumstance that there must be great numbers of men in an army not only ignorant of the Russian and French languages, but unable to read at all. A photograph in this case at once infuses confidence, and prevents the poor journalist being taken into custody, and, perhaps, kept prisoner for days, before a superior officer can be found to decide in the matter. The duties of a special correspondent are, at times, exceedingly likely to lead him to be considered a spy, and thus place him in a position of danger, so that the wearing of a distinctive medal with his own photograph on the reverse, to prove his identity, will frequently stand him in good stead. The application of photography in this case, as a means of identification, is, indeed, one of the happiest that has come under our notice.

FRENCH CORRESPONDENCE.

A TOTAL ECLIPSE OF FOUR DAYS—THE TRUTH OF ASTRONOMICAL PHOTOGRAPHS IMPUGNED—GLASSWOOL FOR FILTERING SILVER BATHS—M. CHARDON'S PROCESS—DETAILS OF M. BOIVIN'S DRY EMULSION PROCESS.

IF we are to believe a communication made, in all seriousness, to the Academy of Sciences on Monday last, by a gentleman whose name unfortunately escaped me, photographers have in prospect several days of enforced holiday, since *la matiere premiere*, as Niepce used to call light, will fail them altogether during that period. It is a question of nothing less than a total eclipse of the sun, which will last for *four consecutive days*, during which the earth will be plunged in total darkness. The author of the communication which contains this revelation (set forth in not less than four pages) bases his statement upon the most certain calculations to guarantee the fact. Here, at any rate, will be a very good opportunity for a trial of Mr. Vanderweyde's system of lighting by means of electricity.

At the same meeting of the members of the Academy, which was rendered particularly mirthful by the strange communication in question, a matter transpired which called attention once more to the value of photography in connection with astronomical observations. I spoke in my last letter of the circumstance of M. Janssen having made a presentation of two pictures of the sun, taken at the Meudon Observatory, which pictures demonstrated the sudden formation of a spot upon the solar disk. Some

gentleman has taken the worthy astronomer to task in reference to the subject, and complains that the latter is desirous of establishing a new theory in respect to the formation of solar spots, which never show themselves, he avows, in a sudden and abrupt manner. To this attack M. Janssen replied that he put forward no theory at all, and that he has simply confined himself to signalling an indisputable fact, since a picture of the sun taken on the 14th of April did not show any spot, whereas that secured upon the 15th, under the same conditions, betrayed the presence of one. This is certainly an argument which cannot be gainsaid, and which is worth more than all the theories put together.

A chemist of Leipsic, M. Paulcke by name, who is now on a visit to Paris, showed me, the other day, some specimens of a very interesting product which has received the name of glasswool. Its aspect is very similar to spun cotton, or rather silk, for the light and delicate fibres of which the tuft was composed were exceedingly brilliant, and of dazzling whiteness. This glasswool is very soft to touch, and extremely light. M. Paulcke proposes this product for use by photographers, and especially for the filtration of nitrate of silver baths.

Appropos of the publication of M. Chardon's process, which is based, as the author acknowledges, upon the employment of a dry emulsion, M. Boivin has communicated to me the method he has employed for some time past for preparing an analogous product—that is to say, pure bromide of silver imprisoned in pyroxyline. Dissolved at once, this product, though possessing certain advantages, has, according to M. Boivin, also serious inconveniences, difficulties in manipulation, loss of time, &c. M. Boivin's process may be summarized as follows:—A glass plate is covered with bromized collodion made up of—

Ether	60 cub. cents.
Alcohol	40 to 50 "
Pulverulent pyroxyline	1.50 grammes
Bromide of zinc or ammonium	1.50 "
Bromide of uranium	1.50 "
Chloride of barium	0.10 "
Alcoholic tincture of bromine	A few drops

The two bromides above indicated may be replaced by 2.50 to 3 grammes of double bromide of cadmium and ammonium, suppressing the chloride of barium. In any case, there is first of all dissolved the salts in the alcohol; the solution is filtered, and the cotton is added after being separated in the ether. The whole is shaken, permitted to settle, and then filtered or decanted in the ordinary manner. The plate coated with collodion is plunged in a silver bath of 20 per cent. strength slightly acidified with nitric acid. It is then washed in several waters, and the film passed into a solution of chloride of zinc made up by dissolving one part of the salt in 1,000 parts of water, after which the plate is again energetically rinsed in water. Finally, by the aid of a short brush, the sensitive film is scrubbed off, which consists of pyroxyline and bromide, and collected in a small quantity of distilled water. After having prepared in this way a certain quantity of the substance, it is washed as well as possible, and dried upon filter paper. M. Boivin assures me that these washings suffice to remove all the injurious salts from the film, so that in the end one has but pure bromide of silver remaining, which is encrusted in pyroxyline. It need not be said that the operations which have just been described must all of them be conducted in the dark, or in a locality illuminated only by yellow light. When it is desired to prepare an emulsion, three grammes of this product are redissolved in—

Ether	50 cub. cents.
Alcohol	45 to 50 "
Morphine, cinchonine, or quinine	0.25 "

After some hours the dissolution of the dry product will be completed, and the emulsion is then filtered through cotton wool. It preserves its sensitiveness unimpaired for a long

time. To prepare dry plates, the glass surface is covered with this sensitive collodion, and the film allowed to dry; but if the collodion is to be used wet, the coated plate is dipped into water for some seconds before being placed in the dark slide, an operation which has the effect of increasing the sensitiveness of the film. Plates prepared with this emulsion may also be covered with an organic preservative. Before proceeding to the development of the film, some ordinary spirits of wine is poured upon the film, which has the effect of dissolving the salts of morphine, cinchonine, or quinine, and to open the pores of the collodion, taking away its property of contraction. A washing in water succeeds, and then the operation of development begins with the aid of an alkaline developer. Although the whole of these operations appear at first sight a little complicated, the employment of dry emulsion avoids the application of preservatives and a series of laborious washings. In fact, the method just described, notwithstanding its apparently elaborate character, is an exceedingly simple one, for the manipulations involved are in no way complicated or tedious to undertake. And for this reason it is an emulsion process which well merits the attention of practical photographers. ERNEST LACAN.

A CHEAP AND EFFECTUAL BURNISHER.

BY NELSON K. CHERRILL.

I HAVE just completed a burnishing-press or roller which has cost me about a pound, and as it works as well as or better than one of an American make which was offered me by a dealer for six pounds ten shillings, a description of it may be of some use to your readers.

I will premise that any one can make a press such as I am about to describe if they will only go about it in the manner pointed out to them. My procedure, then, was as follows:—

I procured, in the first place, a roller—this is made of iron, and turned up true in the lathe. The dimensions are (as shown in the sketch) six and a-half inches long and three inches in diameter. Turned upon each end of

the roller there is a pin half an inch in diameter, and beyond one of them is a square to fit on a handle. The plate is a piece of iron three-quarter inch thick and eight inches long, by six and three-eighths wide. About two inches from one end there is a bar of steel a quarter inch square, brazed on right across the plate thus.

This bar is filed this shape at the top and well burnished all along the upper surface. This burnishing of the steel bar may seem a difficulty to some of the brethren of the camera who are not given to mechanical pursuits. It is in reality very easy of accomplishment. The bar of steel having being filed to its proper shape—care being, of course, taken that the top edge is true, and straight in the direction of the length—needs only to be well rubbed down with fine emery cloth and oil, and then rubbed hard for a few minutes with a rounded piece of bright steel, as, for instance, the back of a gouge; in a few minutes this will produce an admirable burnish, well suited to the requirements of the case.

To mount and complete the press I procured a piece of wood eighteen inches long, two and a-half inches thick,

and seven inches wide (the length being to secure greater steadiness). In the centre on each side there is an upright raised. Being let in, and screwed into the base, near the top of these there are two holes, in which fit with some accuracy the ends of the roller, the one with a square

projecting far enough through to admit of the handle being fastened on. (The handle is not shown in the sketch). When in its place, the bottom of the roller should be about two inches from the top of the base board. The plate is supported underneath the roller by means of three three-inch screws, which are shifted up and down by means of a screw-driver, till the plate being put in position, there is an equal slit or opening between the roller and the burnished steel bar of about the thickness of a mounting card. A stop of wood screwed on to the base-board prevents the plate slipping out of position when the press is used.

To use the press, I take out the iron plate, and place it over a Bunsen gas-burner till hot enough; when heated I carefully wipe the burnisher before replacing it in the machine. I find that one heating will enable me to burnish about three dozen cartes; after this, if the highest polish be desired, the plate must be re-heated: a very little practice will serve to show how hot the plate must be made. The advantage gained by having the plate so thick and large is, that being once heated it retains the heat for long enough to enable a considerable number of prints to be rolled. In those presses in which a lamp is placed underneath the plate as it stands in the machine, I have noticed a difficulty caused by the water of combustion condensing on the roller-plate, &c., and thereby causing rust, if not carefully wiped up each time the press is used. If on the first trial the roller refuses to draw the card over the surface of the burnisher, it will be necessary to take a rough file and scratch the surface of the roller in all directions; this will render the "bite" quite satisfactory; but it will probably be unnecessary to do this unless the roller has been turned to a very fine surface. The essentials of this press are the true turning of the roller, and the straight, well-burnished edge over which to draw the print; the pressure needed in hot burnishing is so much less than in rolling in the old-fashioned way, that the wooden supports and bed are quite strong enough.

After my press had been in use a few days, I found the cards much scratched; on attempting to burnish them, I found then that a little piece of oilstone rubbed over the surface of the burnisher gave an excellent surface which, though not a true burnish, is yet so smooth that the carte takes a perfect gloss on being rolled over it.

In finishing prints with the burnishing press, it is best to retouch after the burnish is given, as the machine has some tendency to rub off the brush work.

SAFETY OXYGEN GENERATOR.

BY W. J. CHADWICK.

SINCE I introduced to the meeting of the Manchester Photographic Society, two months ago, my oxygen generator, I have thought proper to modify its construction, making it into a safety apparatus, by the use of which explosions or accidents are next to impossible. The retort or generator is in form very similar to that first introduced, but the difference is in the mode of fastening. From the accompanying drawings (figs. 1 and 2) it will be seen that the retort is formed of two pieces; a flat plate, A, and a cap, B, which has an aperture at the top, into which is

screwed the pipe for carrying away the gas. In other respects they are two simple castings, ground to a gas-tight

Fig. 1.

Fig. 2.

fit (a very simple matter), and if ever required can be renewed at a cost of about half a crown. The cap B is weighted by two spiral springs at the extremities of the bow, C, to about seven pounds dead weight, which, on a three-inch diameter retort, is equal to one pound pressure per square inch, or twenty-seven and a-quarter inches water pressure, and as it is not usual to use more than from five to six inches of water pressure (or less than a quarter-pound per square inch) in a gas-holder for oxyhydrogen lime light, I consider the one pound sufficient margin for excess.

Now it is obvious that if the passage from the generator to the gas-holder be stopped up, either by omitting to open the tap, or from any other cause (such *has* been the case, and, in some instances, nearly caused fatal accidents), the pressure in the generator would soon rise, and when it had arrived at the pound pressure would lift the cap and allow the gas to escape, on the same principle exactly as the safety-valve of a steam boiler, but with less force, for one pound pressure out of a three-inch diameter safety valve would be hardly noticeable. Now as soon as the passage is again clear, the gas would take its right course, relieving the pressure inside the retort, and by virtue of the springs the top would assume its original position. This method of weighting the retort by springs forms an excellent mode of attachment.

To open the apparatus, pull over the wooden handle which is fixed on the top of bow C, and the cap B may be lifted off by the handle thereto. For closing the retort, reverse the operation, which is almost instantaneous, and far superior to any method of screwing.

It will be seen that I use an ordinary Bunsen burner; Wallace's, with a perforated cap, I find the best, the heat from which is generated far above the springs which act as weights, and therefore are not likely to get hot and lose their temper.

The chlorate of potash and manganese are mixed and formed into cakes, which, when dry, are quite hard, and not at all fragile, as some people have supposed; they are extremely clean to handle, and the making of them is not the "dirtiest of dirty jobs," for with a basin, a knife, a mould, and a little gum water, they can be made almost without soiling the fingers. Since I first introduced the cakes I find the substratum of manganese not necessary, as if the cakes are dry they do not stick to the apparatus objectionably, being only in contact with the retort bottom, which is made convex, so that the cakes shall not bear all over. By this precaution the spent cakes may be removed from the retort in their entirety, slightly distended, but otherwise in their original form.

As more chlorate of potash can be got into less bulk in the cake form than loose powdered chlorate, it is obvious that more gas can be generated with fewer charges, one cake three inches diameter and one inch thick being equal

to a plug one inch diameter and nine inches long, or about two ordinary plug charges.

I exhibited this apparatus at work before the members of the Manchester Photographic Society; the time from the lighting of the burner until the gas began to generate was one and three-quarter minutes, or about one-third of the time of another apparatus then and there tried.

To illustrate the safety of the apparatus at the above exhibition: as the gas was coming off rapidly, the outlet was closed, and the gas was still generating and escaping through the joint, as intended, with perfect safety.

There are other methods of weighting the retorts, as shown in the two drawings (fig. 3, dead weight; fig. 4, lever

Fig. 3.

Fig. 4.

and weight). In these cases the weights might be utilised for weighting the gas-holder, but I prefer the apparatus with springs, and to weight the gas-holder with water in a reservoir at the top of the gas-holder placed there for that purpose.

THE PARIS DRY PLATE COMPETITION.

M. CHARDON'S PROCESS.*

THE excess of nitrate of silver passes into chloride of silver; the excess of chloride of cobalt is eliminated by the washings which follow, and the operator approaches as far as possible towards the theoretical production of pure bromide of silver. It is as well to test after an hour or two of contact, in order to see if a sufficient quantity of soluble chloride has been added, and that there remains no excess of free nitrate of silver, for even after repeated washings the excess of nitrate of silver may prevent the preservation of the product.

The mixture thus obtained contains, besides bromide of silver and pyroxyline, nitrates of zinc, cadmium, ammonium, and cobalt, and chloride of cobalt, which it is well to get rid of by precipitation.

The collodion is poured gradually, little at a time, into a large quantity of distilled water; after agitation, the precipitate is collected upon a piece of fine linen in a funnel. You repeat as many times as it is necessary to precipitate all the collodion, and each precipitate, as it is recovered, is added to that in the funnel; washing with abundance of water succeeds, until the water passes off perfectly pure, and then you drain, press, and spread the substance upon stout filter paper, where it is dried in complete obscurity.

The product should be a flocculent matter of a clear yellow colour and very light, and constitutes the dry emulsion. To prepare the plates, there is taken:

Ether	50 cub. cent.
Alcohol	50 "
Cinchonine (or precipitated quinine)	0.20 "

You commence by dissolving the cinchonine in alcohol

* Continued from page 246.

(according to recent experiences, M. Chardon prefers quinine), and after filtering, 3.50 grammes of the dry emulsion are put into a mixture of the two liquids. This quantity is only nominal, and varies according to the viscid nature of the sensitive collodion that results; the mixture is vigorously shaken several times, and, after some hours, filtered through cotton wool, when it is ready for use.
